## Hall-Hérault Cell Advanced Modelling Development

Dr. Marc Dupuis

**GENISIM**

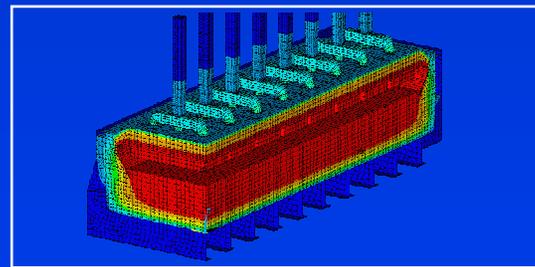

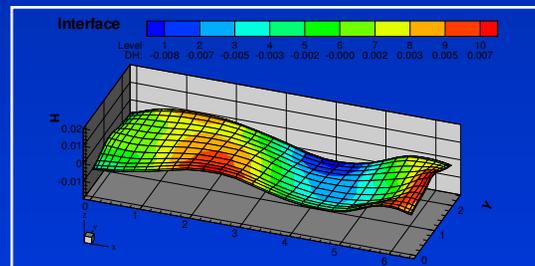

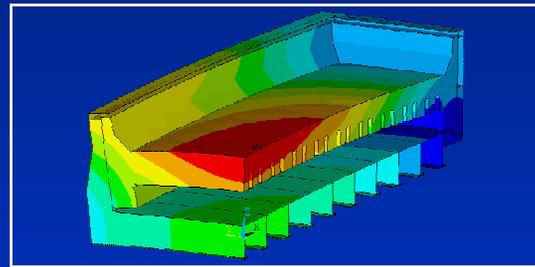

---

**GENISIM**

# Introduction

In general, we can fit Hall-Héroult cell mathematical models into three broad categories:

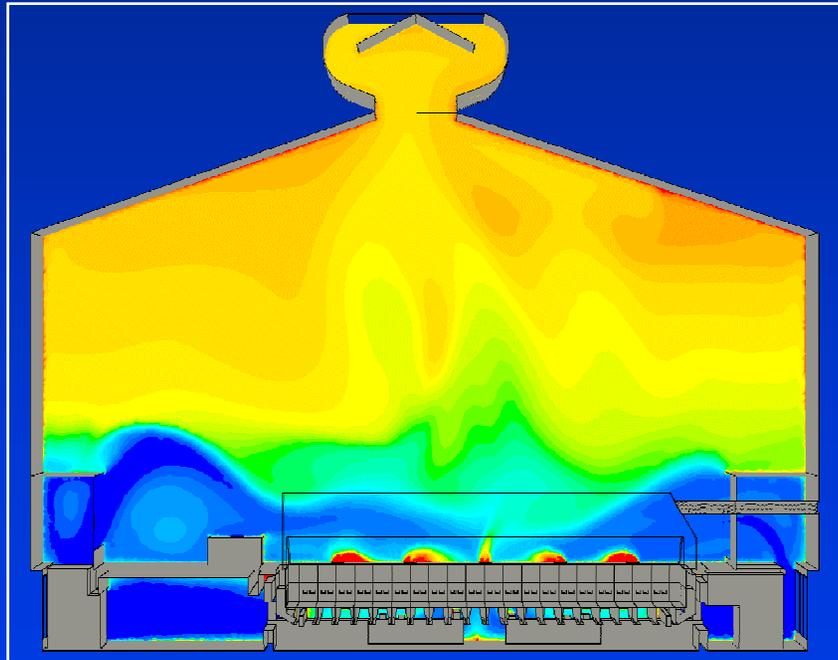

- Stress models which are generally associated with cell shell deformation and cathode heaving issues.
- Magneto-hydro-dynamic (MHD) models which are generally associated with the problem of cell stability.
- Thermal-electric models which are generally associated with the problem of cell heat balance.

Cell  
Design

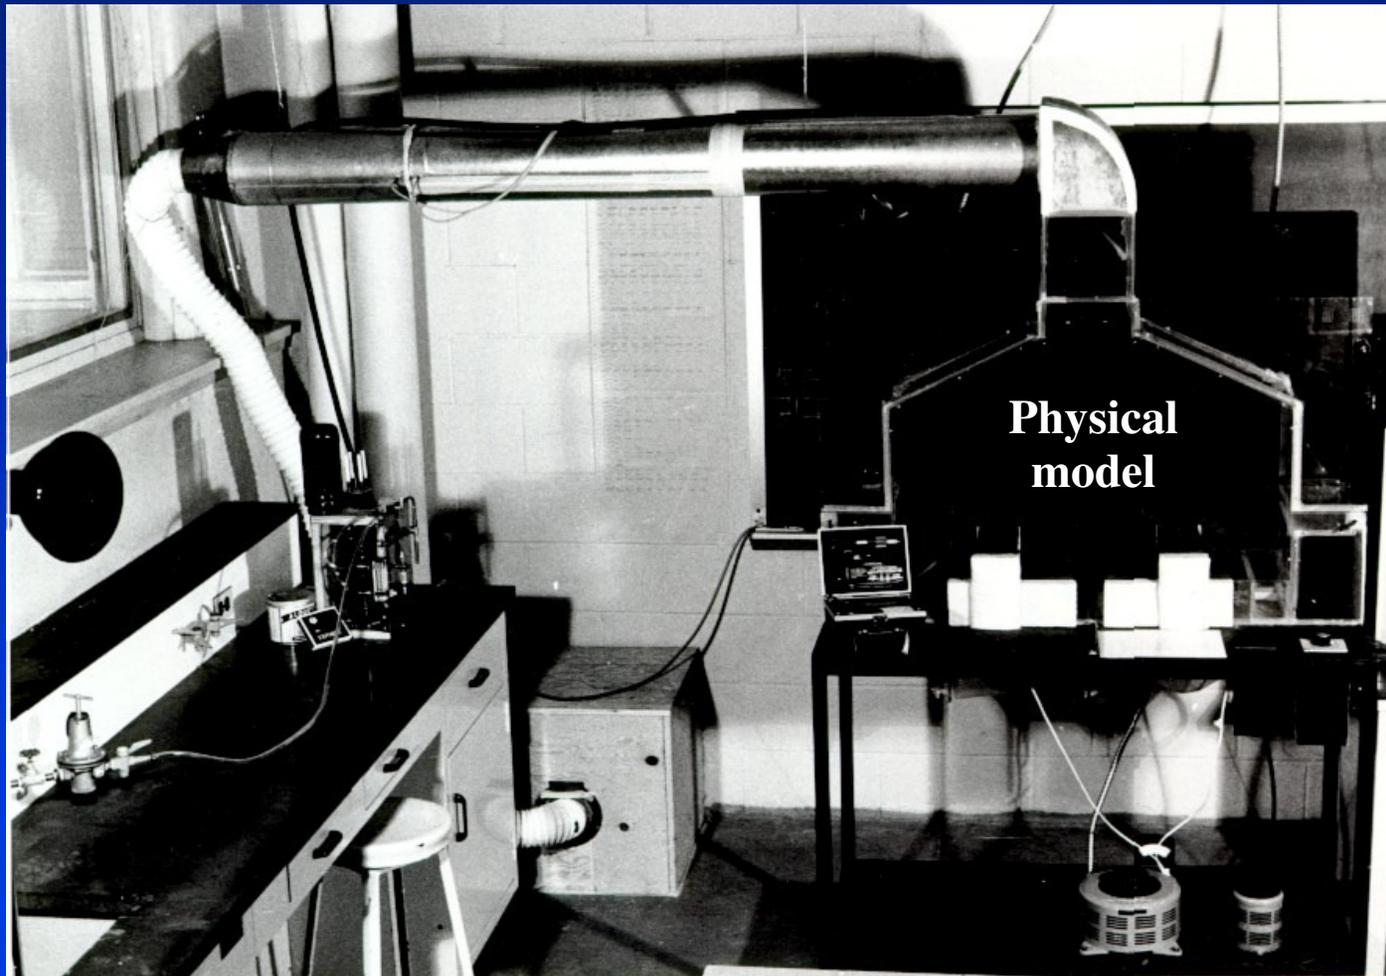

# Introduction

The design of the smelter potroom building requires a forth categorie of models:

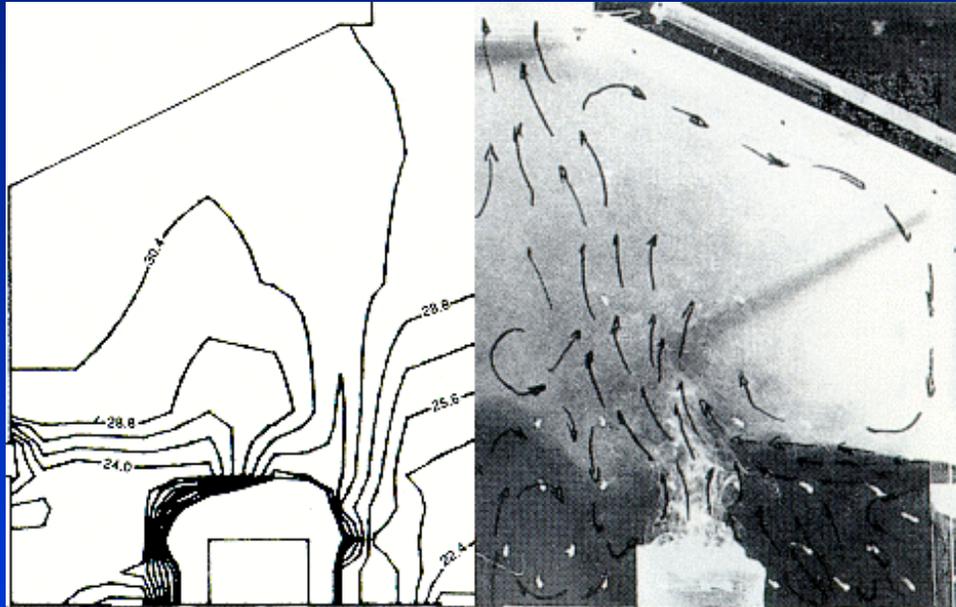

Potroom  
Design

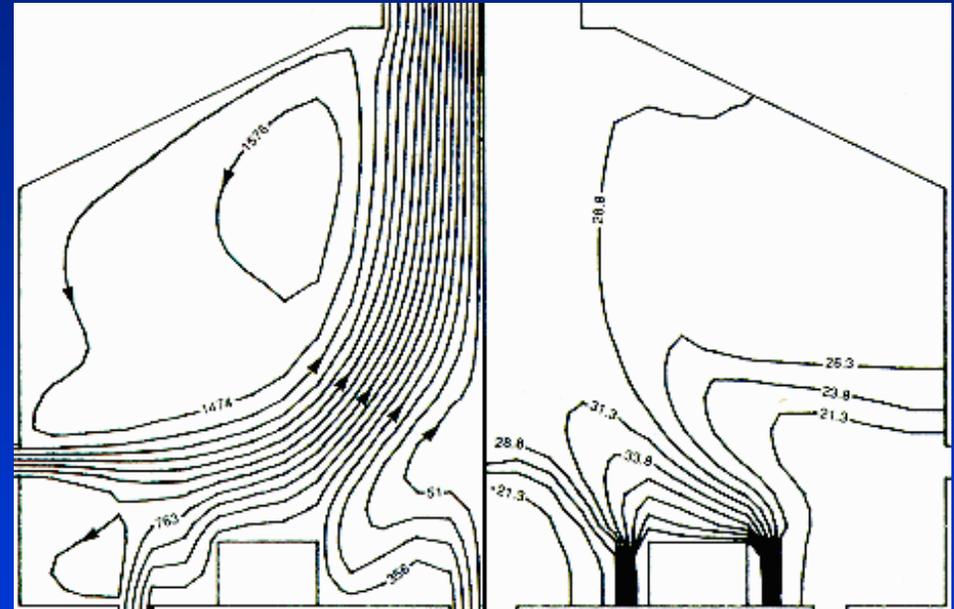

# 1980-84, 2D potroom ventilation model

# 1980-84, 2D potroom ventilation model

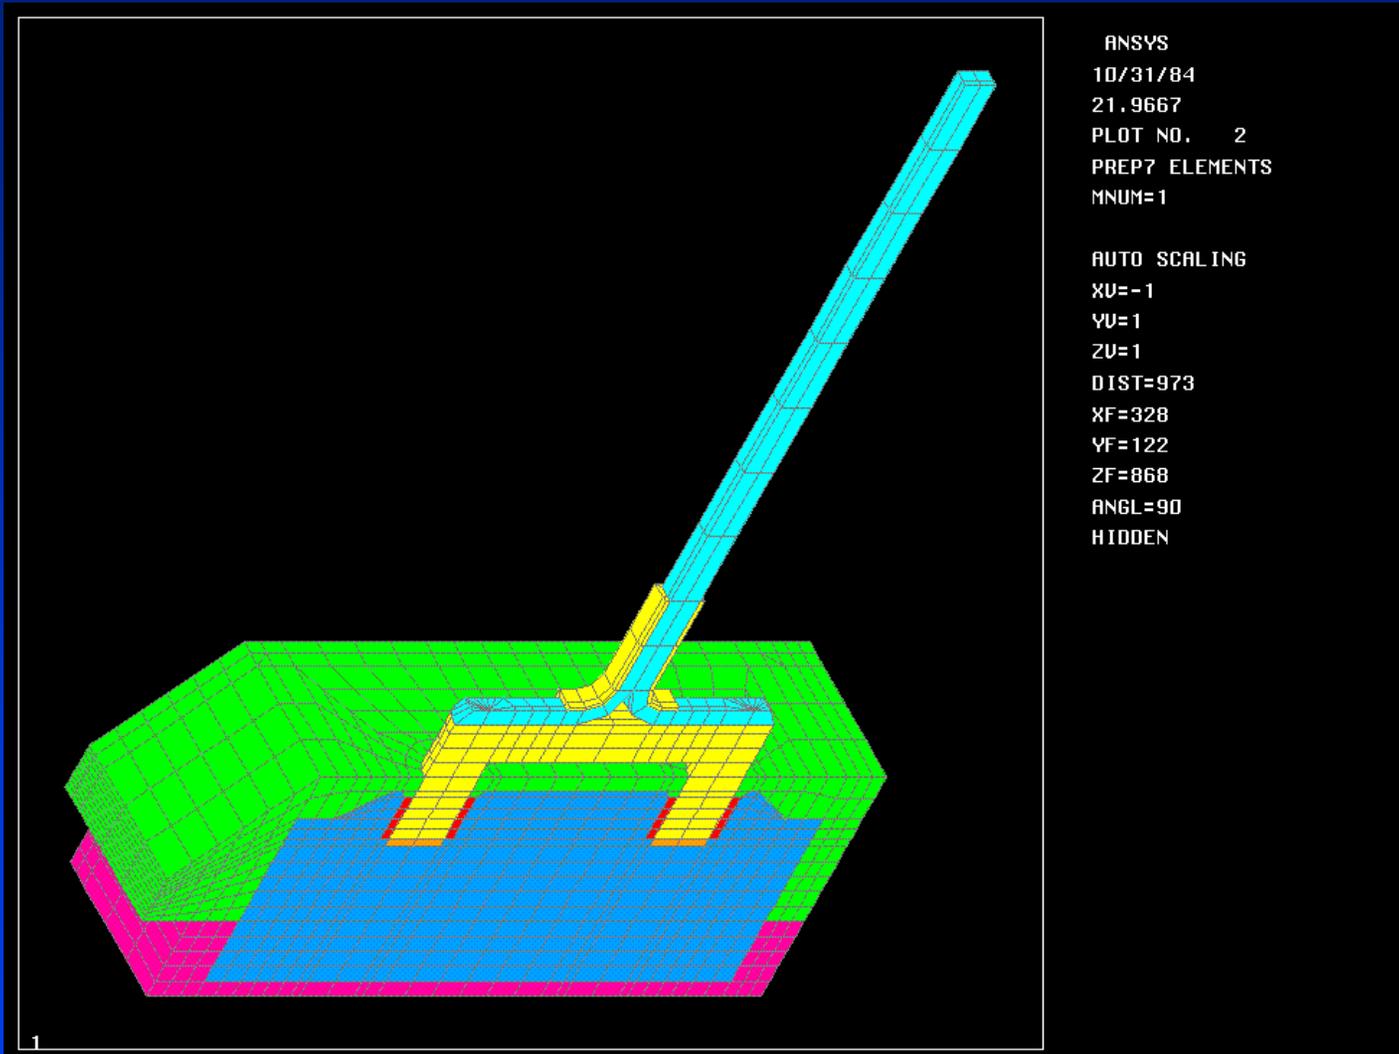

Experimental results

Best model results

The best results of my Ph.D. work: the 2D finite difference vorticity-stream function formulated model could not reproduce well the observed air flow regardless of the turbulence model used.

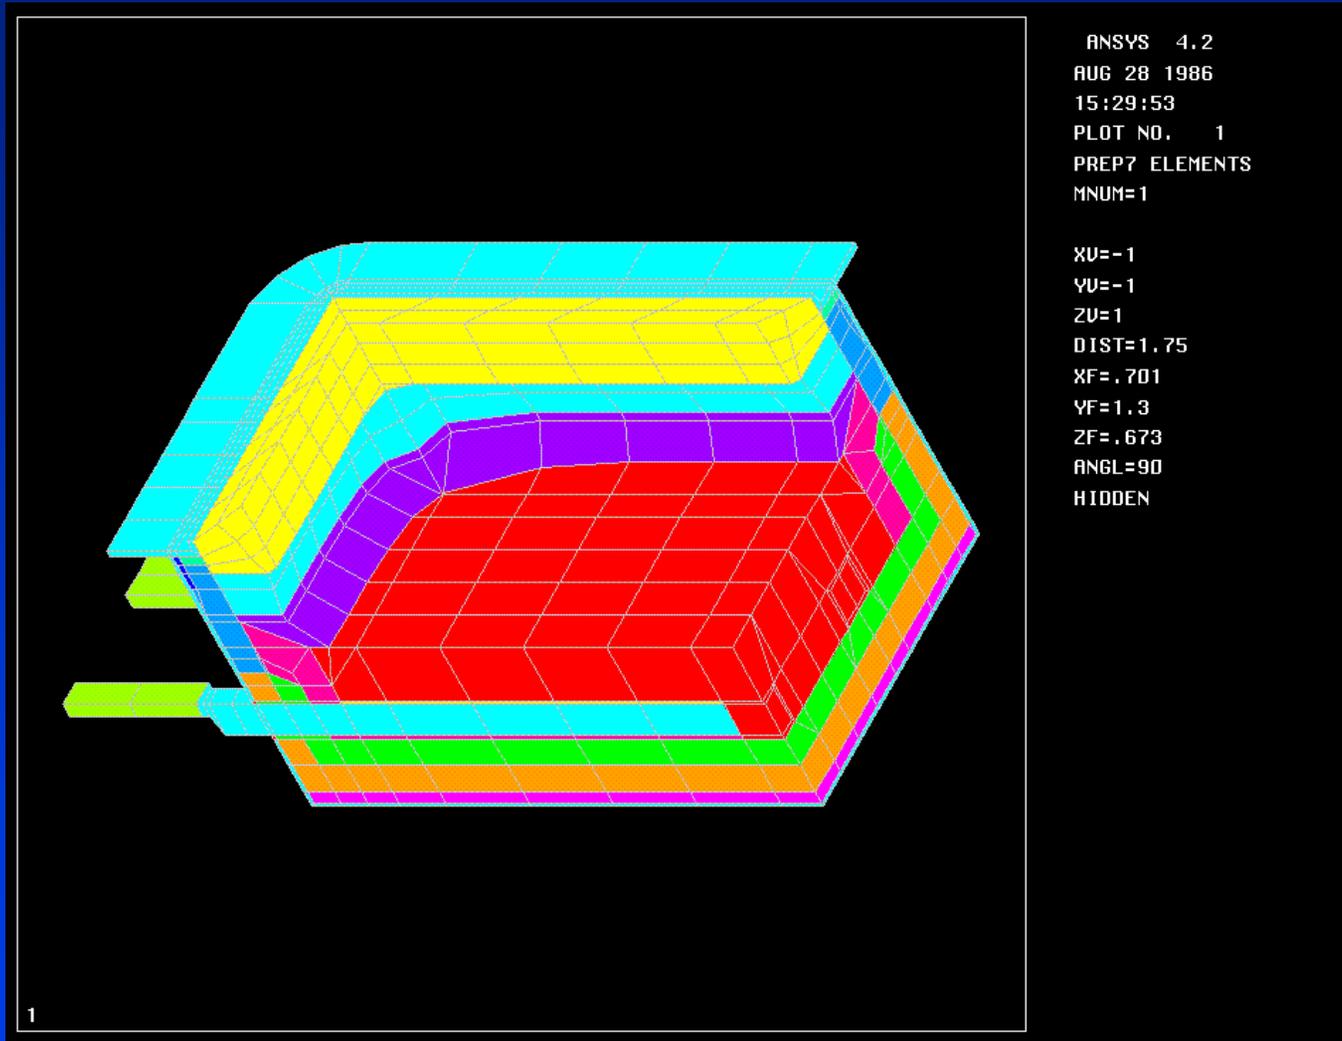

# 1984, 3D thermo-electric half anode model

That model was developed on ANSYS 4.1 installed on a shaded VAX 780 platform.

That very first 3D half anode model of around 4000 Solid 69 thermo-electric elements took 2 weeks elapse time to compute on the VAX.

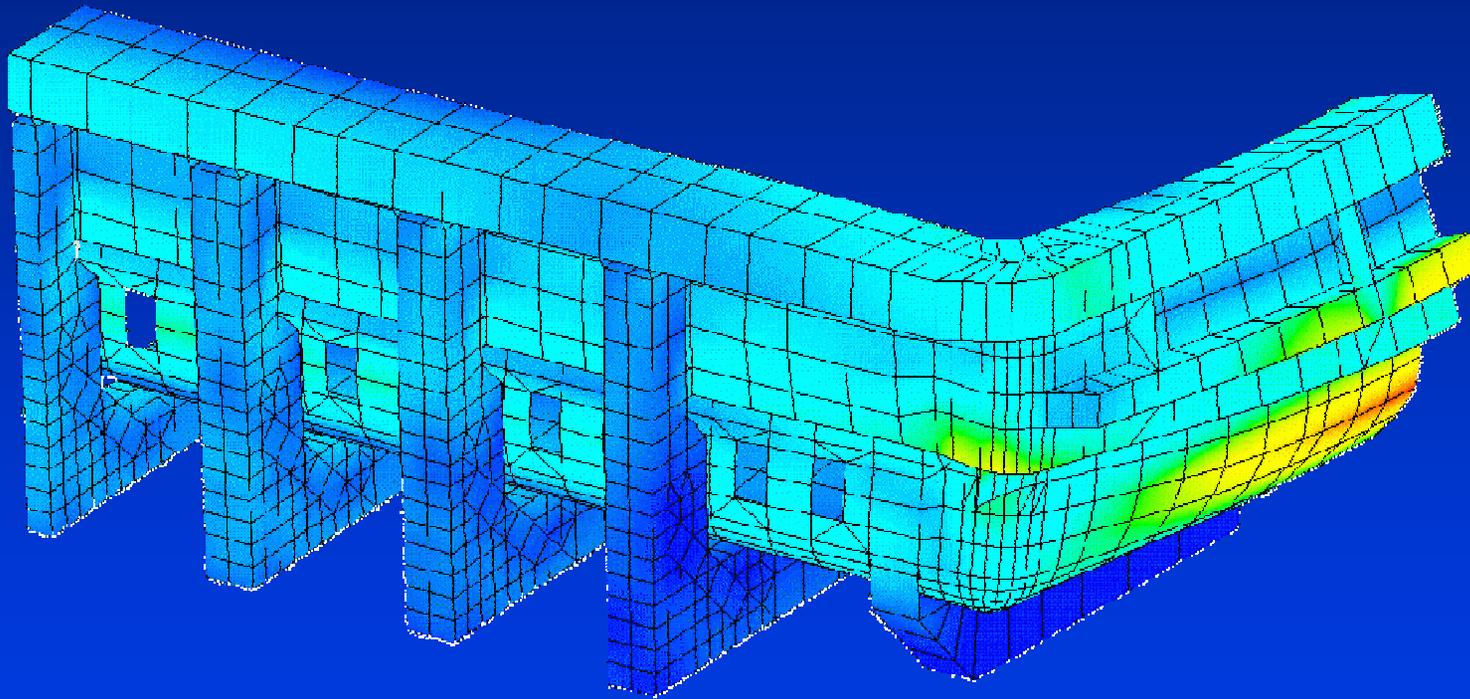

# 1986, 3D thermo-electric cathode side slice and cathode corner model

The next step was the development of a 3D cathode side slice thermo-electric model that included the calculation of the thickness of the solid electrolyte phase on the cell side wall .

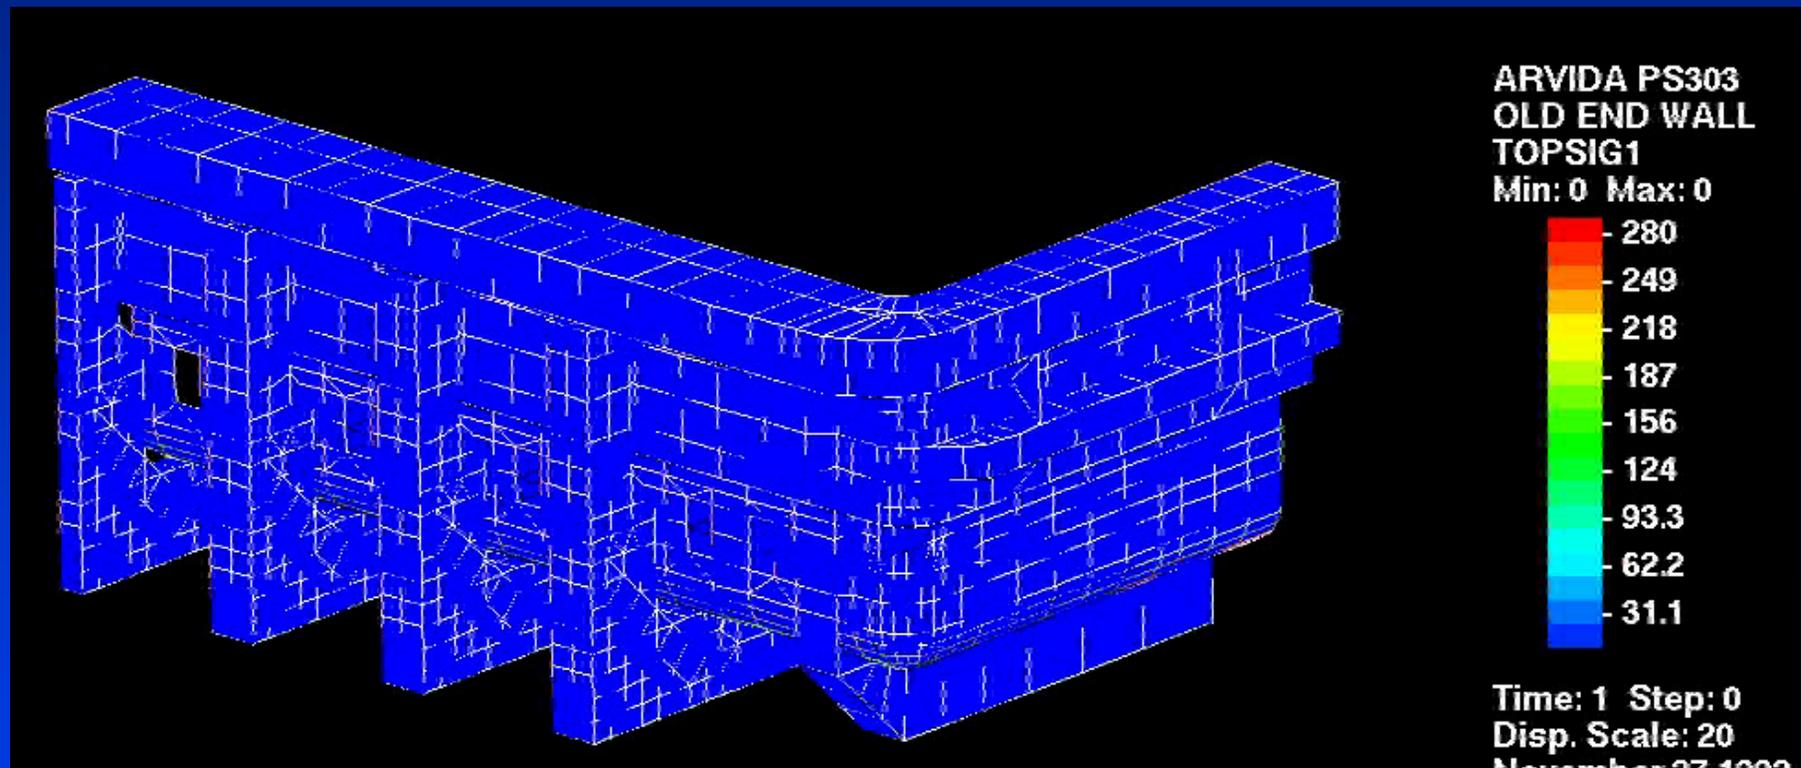

Despite the very serious limitations on the size of the mesh, a full cathode corner was built next .

# 1988, 3D cathode potshell plastic deformation mechanical model

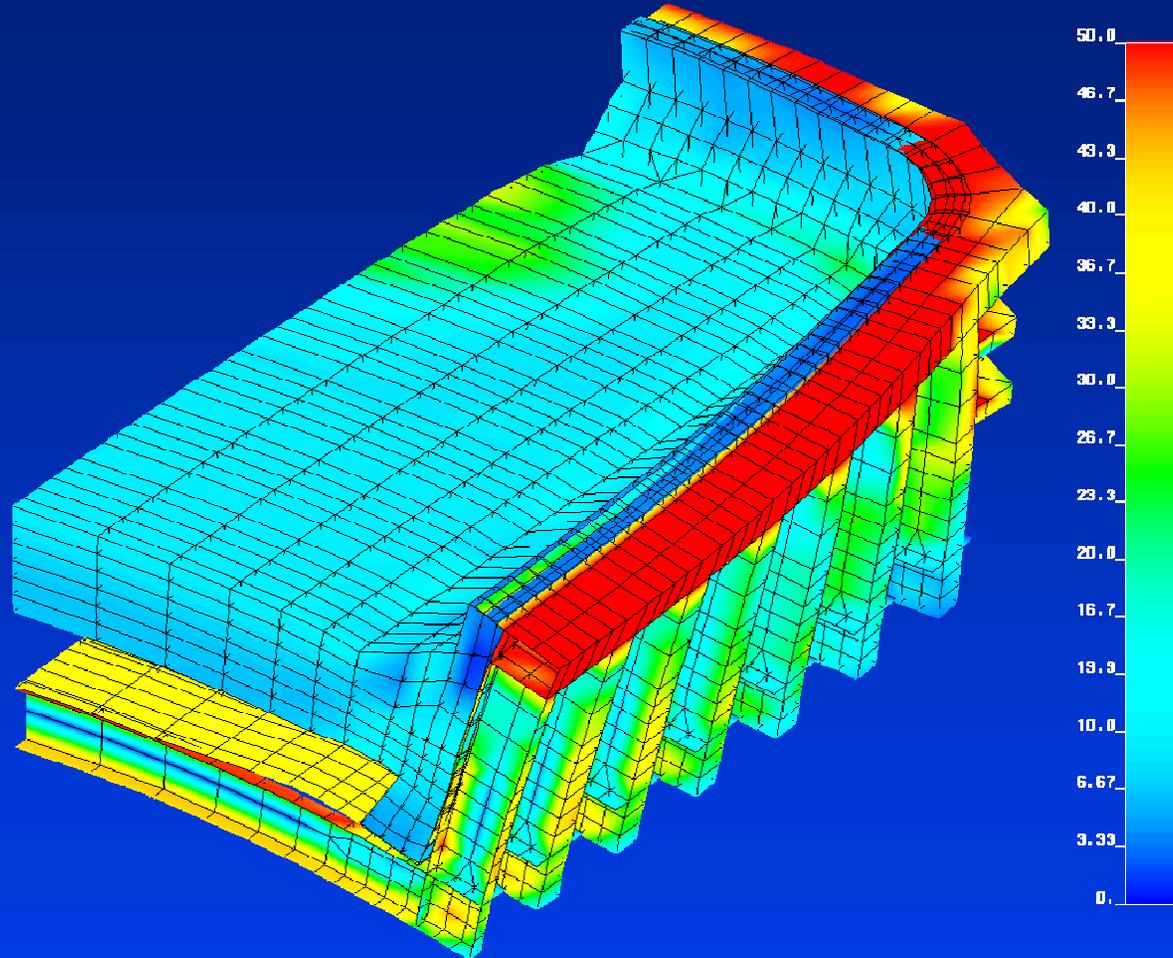

The new model type addresses a different aspect of the physics of an aluminum reduction cell, namely the mechanical deformation of the cathode steel potshell under its thermal load and more importantly its internal pressure load .

# 1988, 3D cathode potshell plastic deformation mechanical model

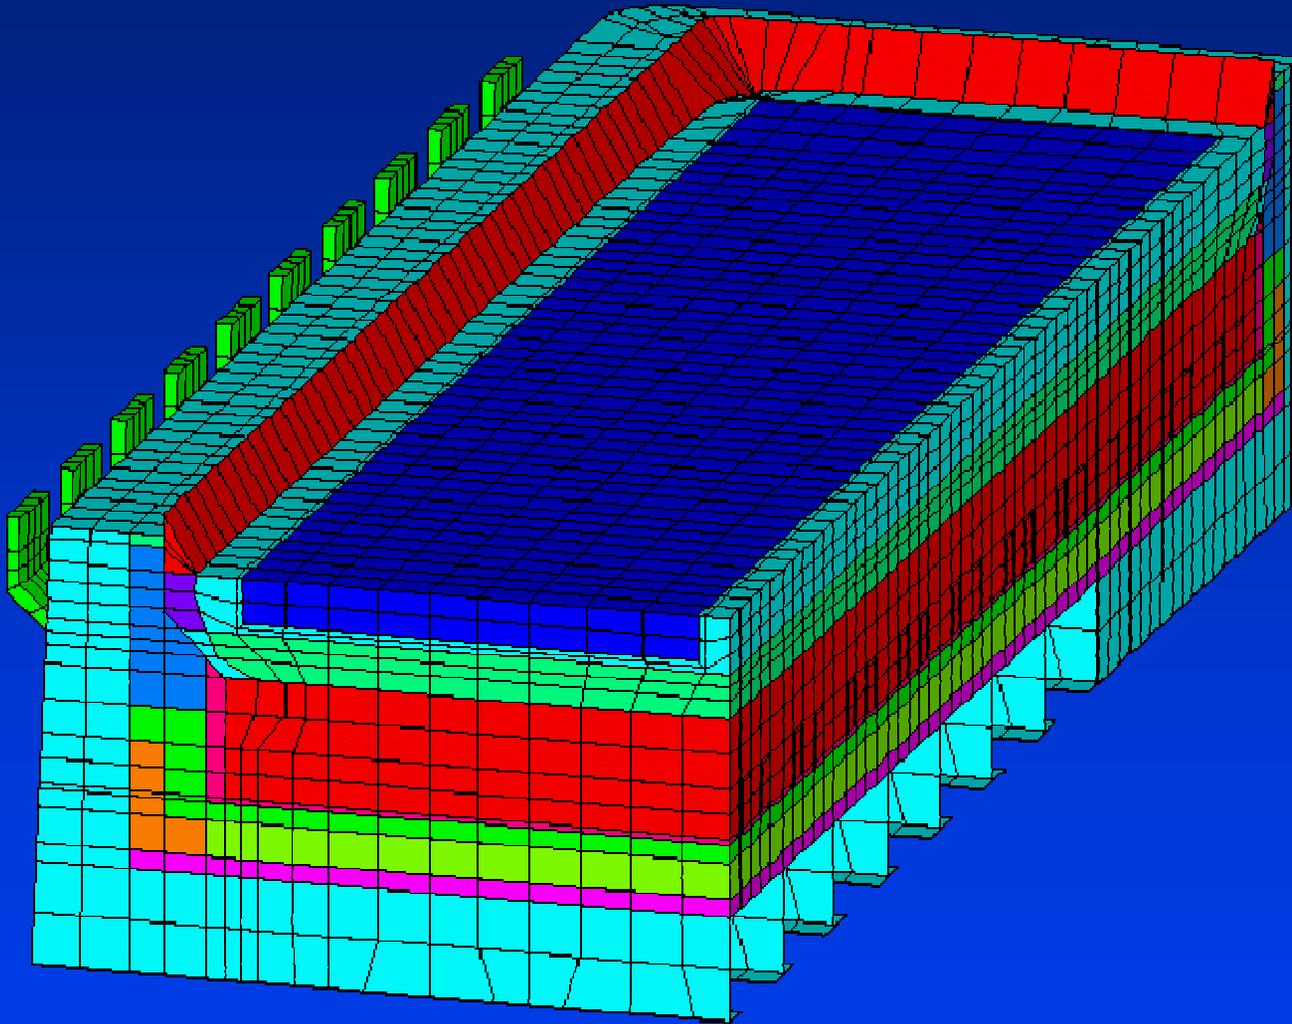

# 1989, 3D cathode potshell plastic deformation and lining swelling mechanical model

First “Half Empty shell” potshell model developed in 1989 and presented at a CRAY Supercomputing Symposium in 1990

**GENISIM**

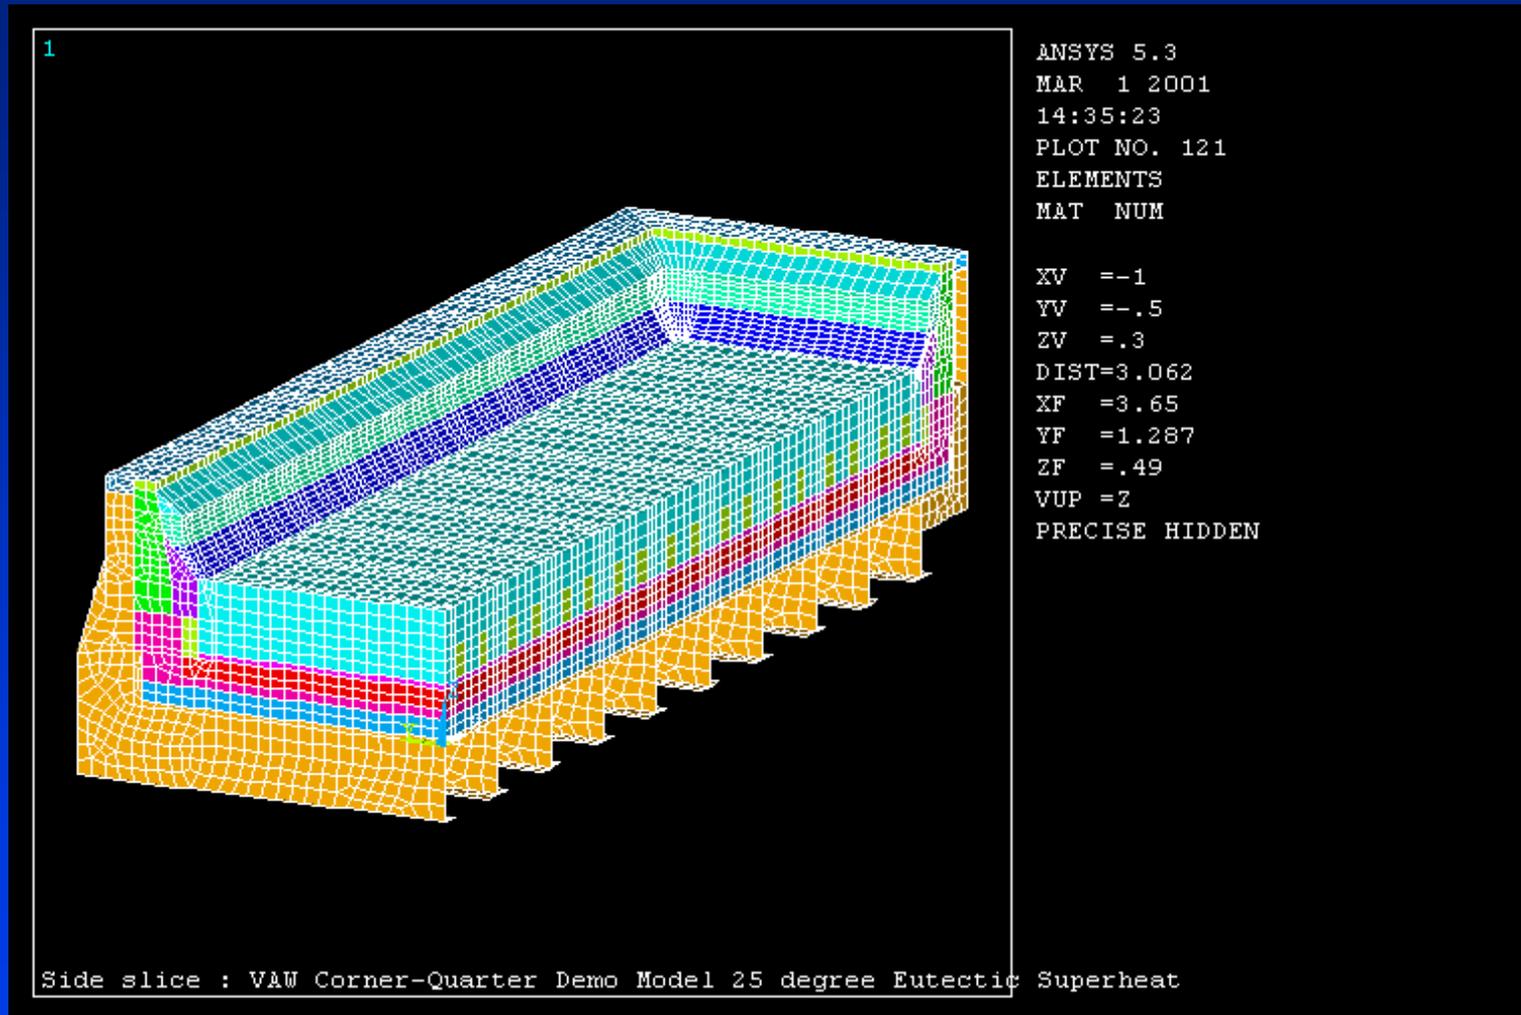

# 1992, 3D thermo-electric quarter cathode model

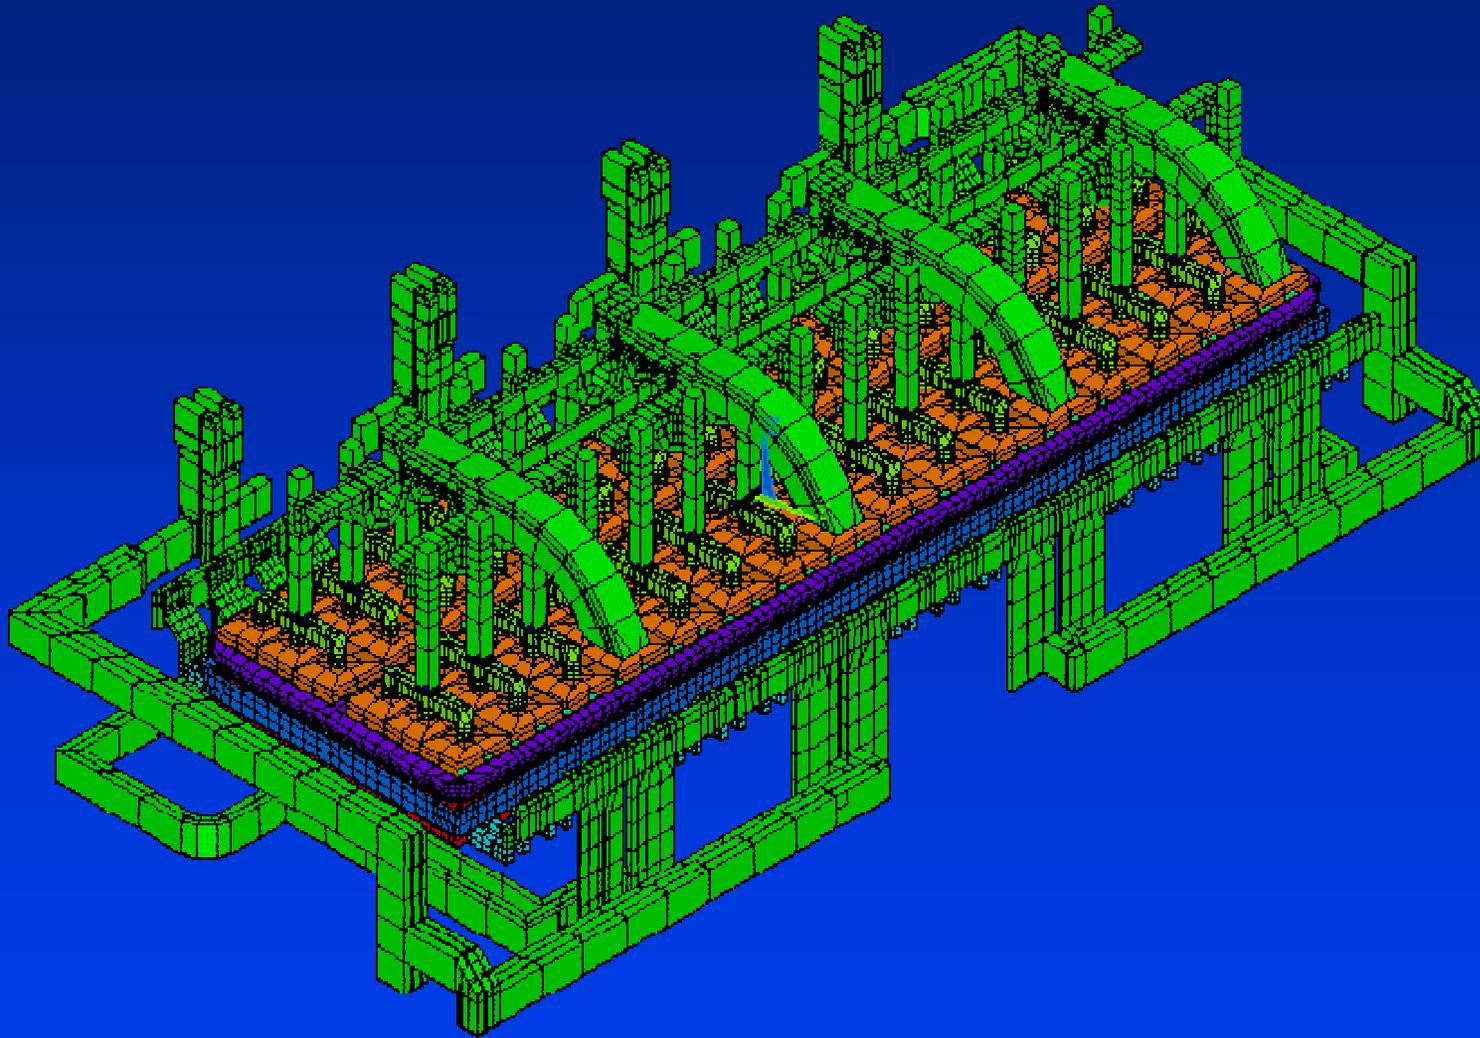

With the upgrade of the P-IRIS to 4D/35 processor, and the option to run on a CRAY XMP supercomputer, the severe limitations on the CPU usage were finally partially lifted.

This opened the door to the possibility to develop a full 3D thermo-electric quarter cathode model.

# Full Cell Quarter Thermo-Electric Model

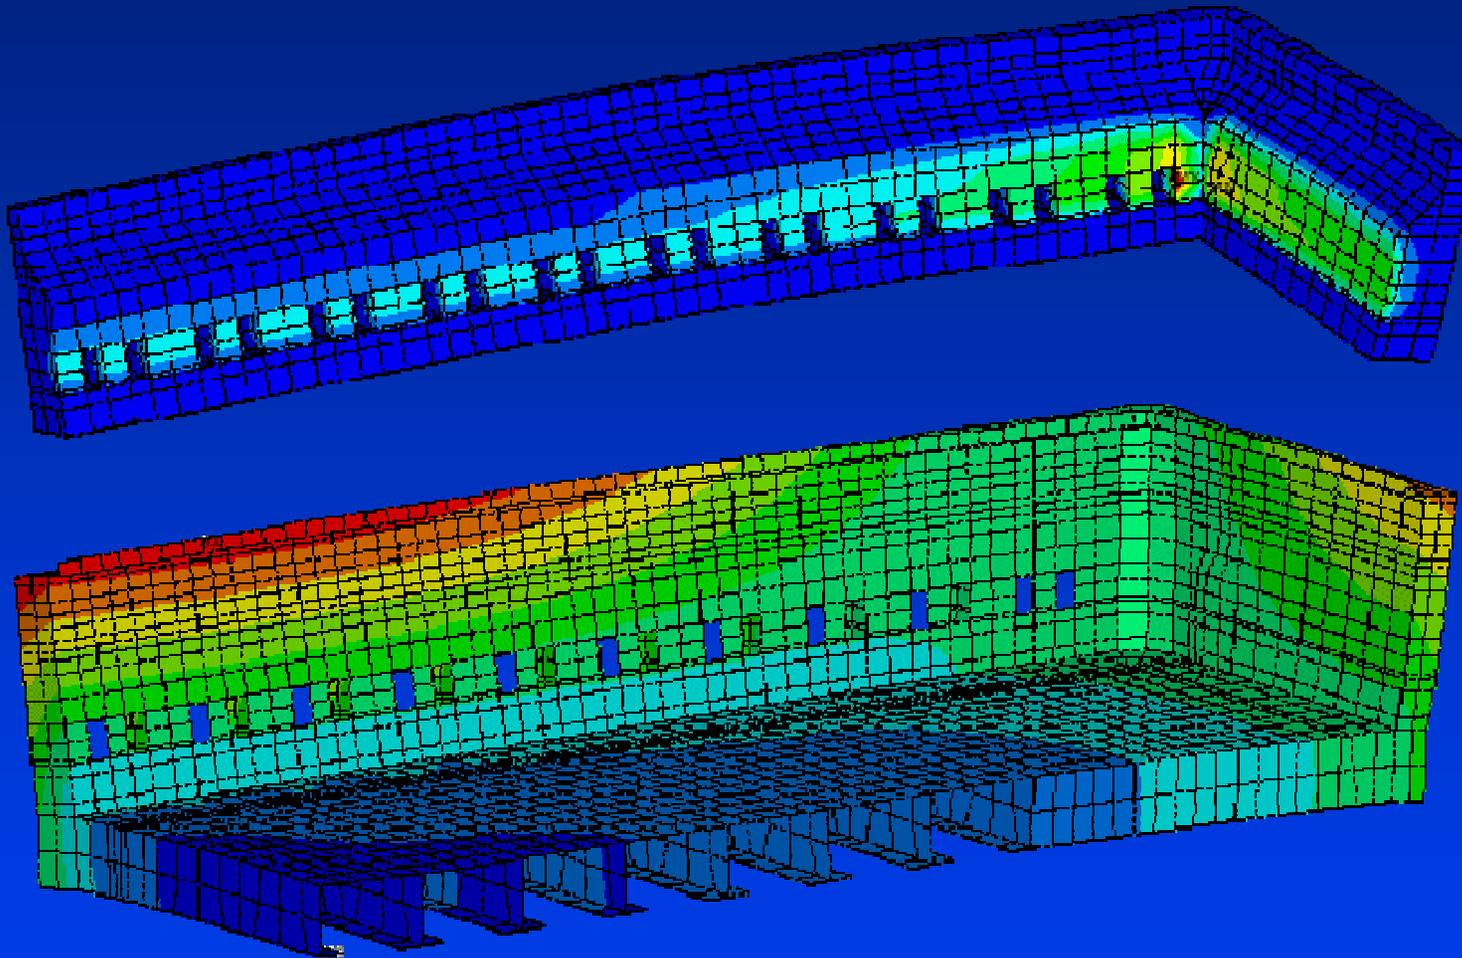

# 1992, 3D thermo-electric “pseudo” full cell and external busbars model

As a first step toward the development of a first thermo-electro-magnetic model, a 3D thermo-electric “pseudo” full cell and external busbars model was developed.

That model was really at the limit of what could be built and solved on the available hardware at the time both in terms of RAM memory and disk space storage.

# 1992, 3D cathode potshell plastic deformation and lining swelling mechanical model

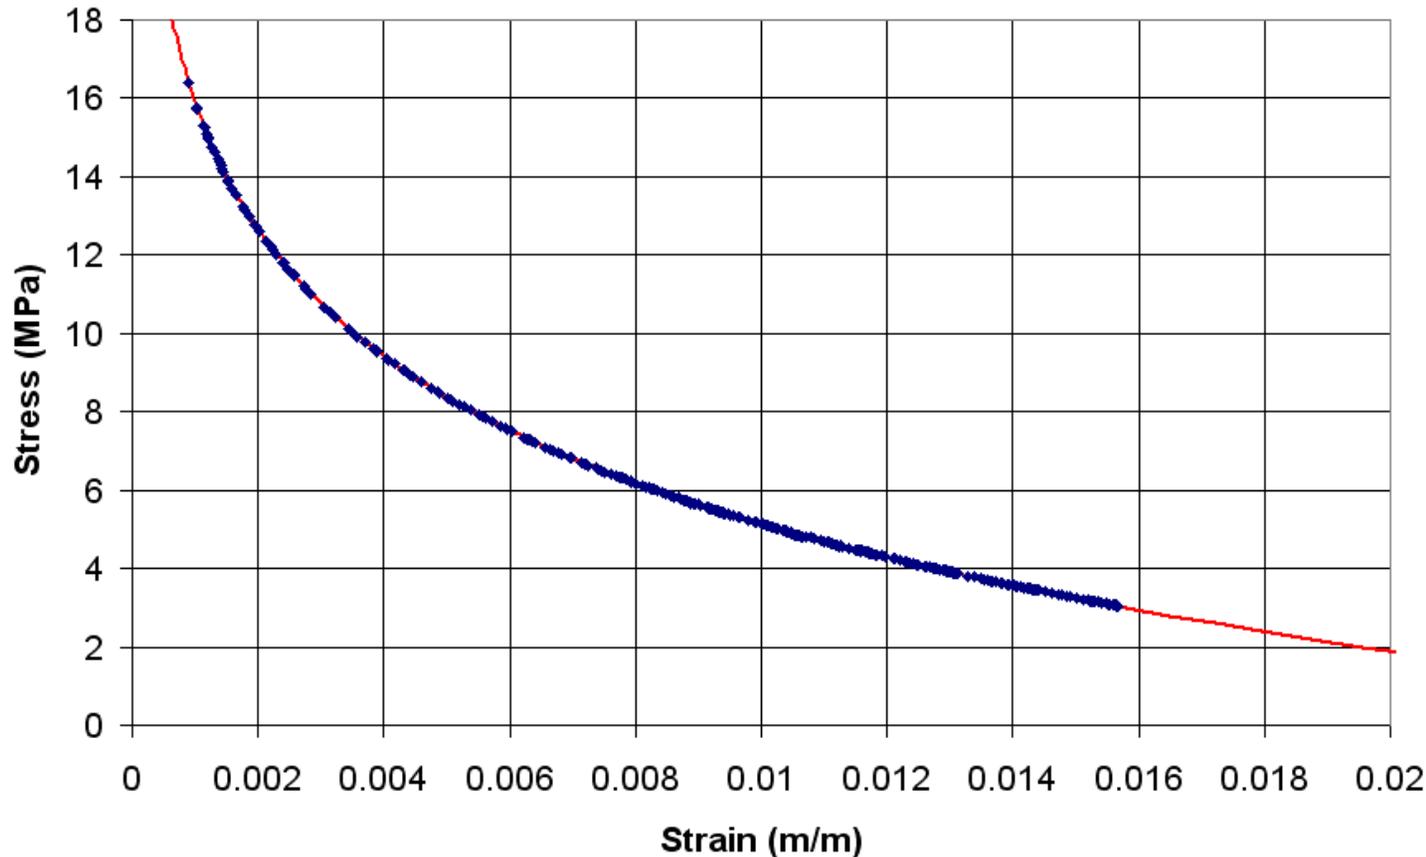

The empty quarter potshell mechanical model was extended to take into account the coupled mechanical response of the swelling lining and the restraining potshell structure.

That coupling was important to consider as a stiffer, more restraining potshell will face more internal pressure from the swelling lining material.

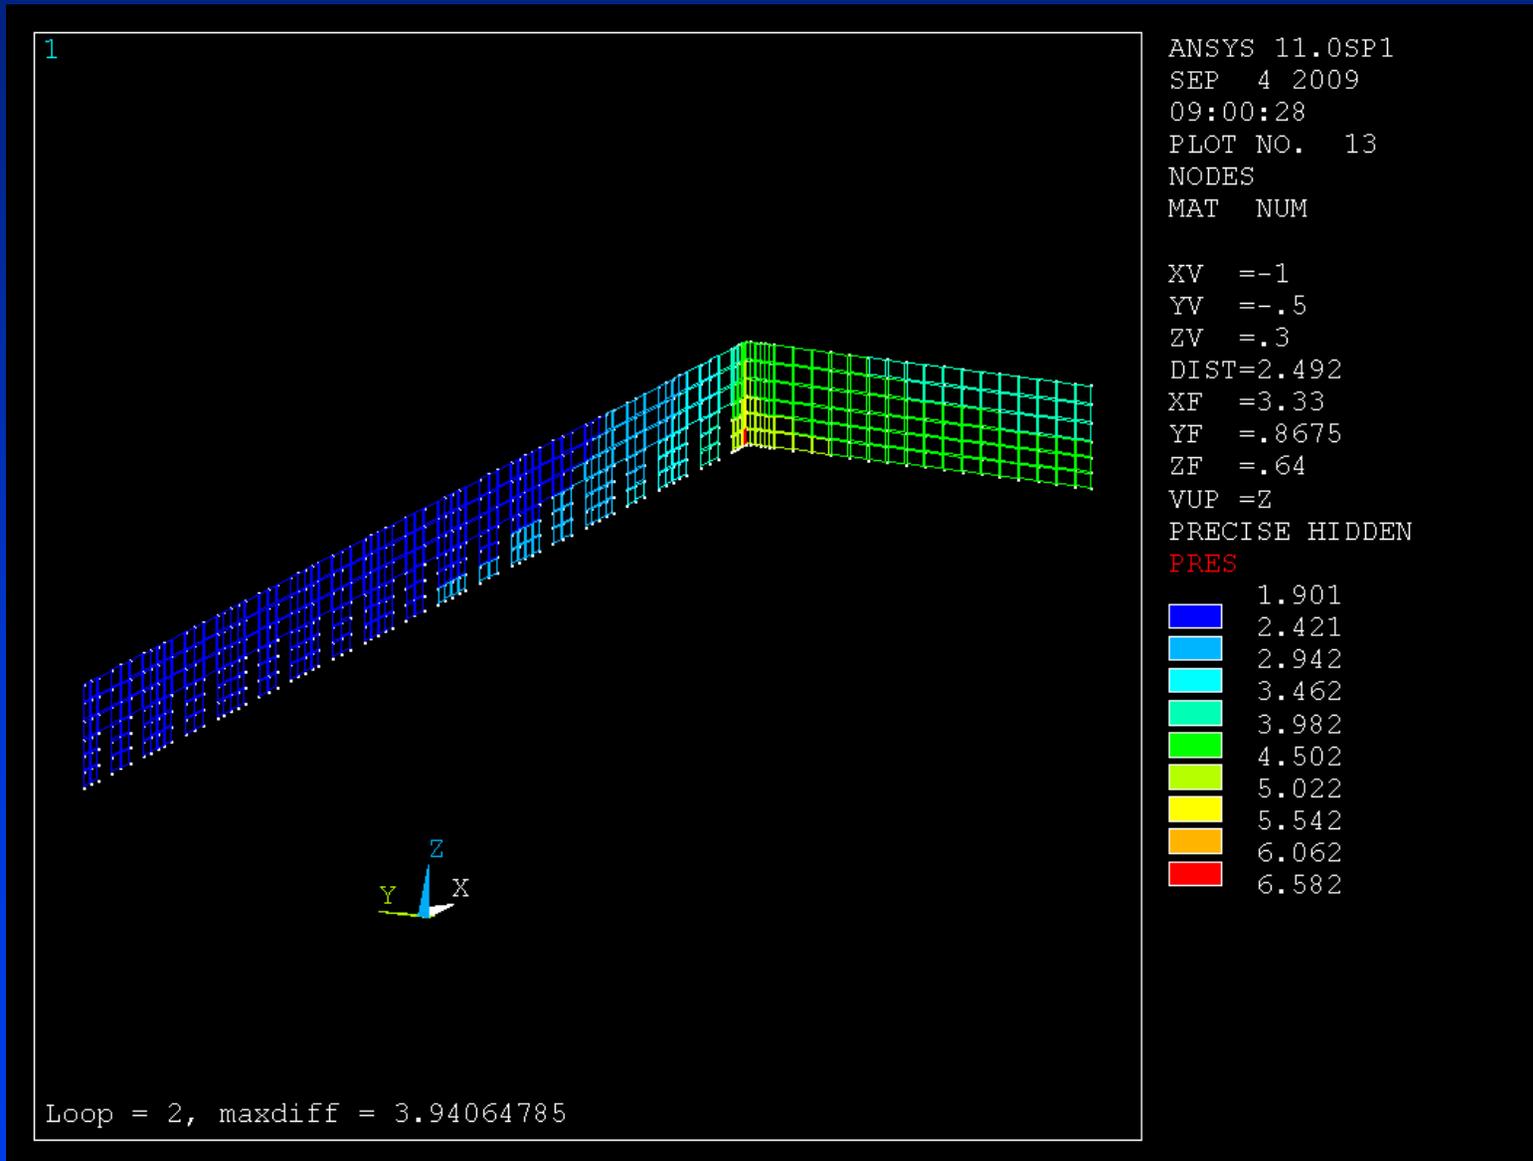

# 1992, 3D cathode potshell plastic deformation and lining swelling mechanical model

Individual element face strain-stress location on the Dewing curve  
Elastic mode

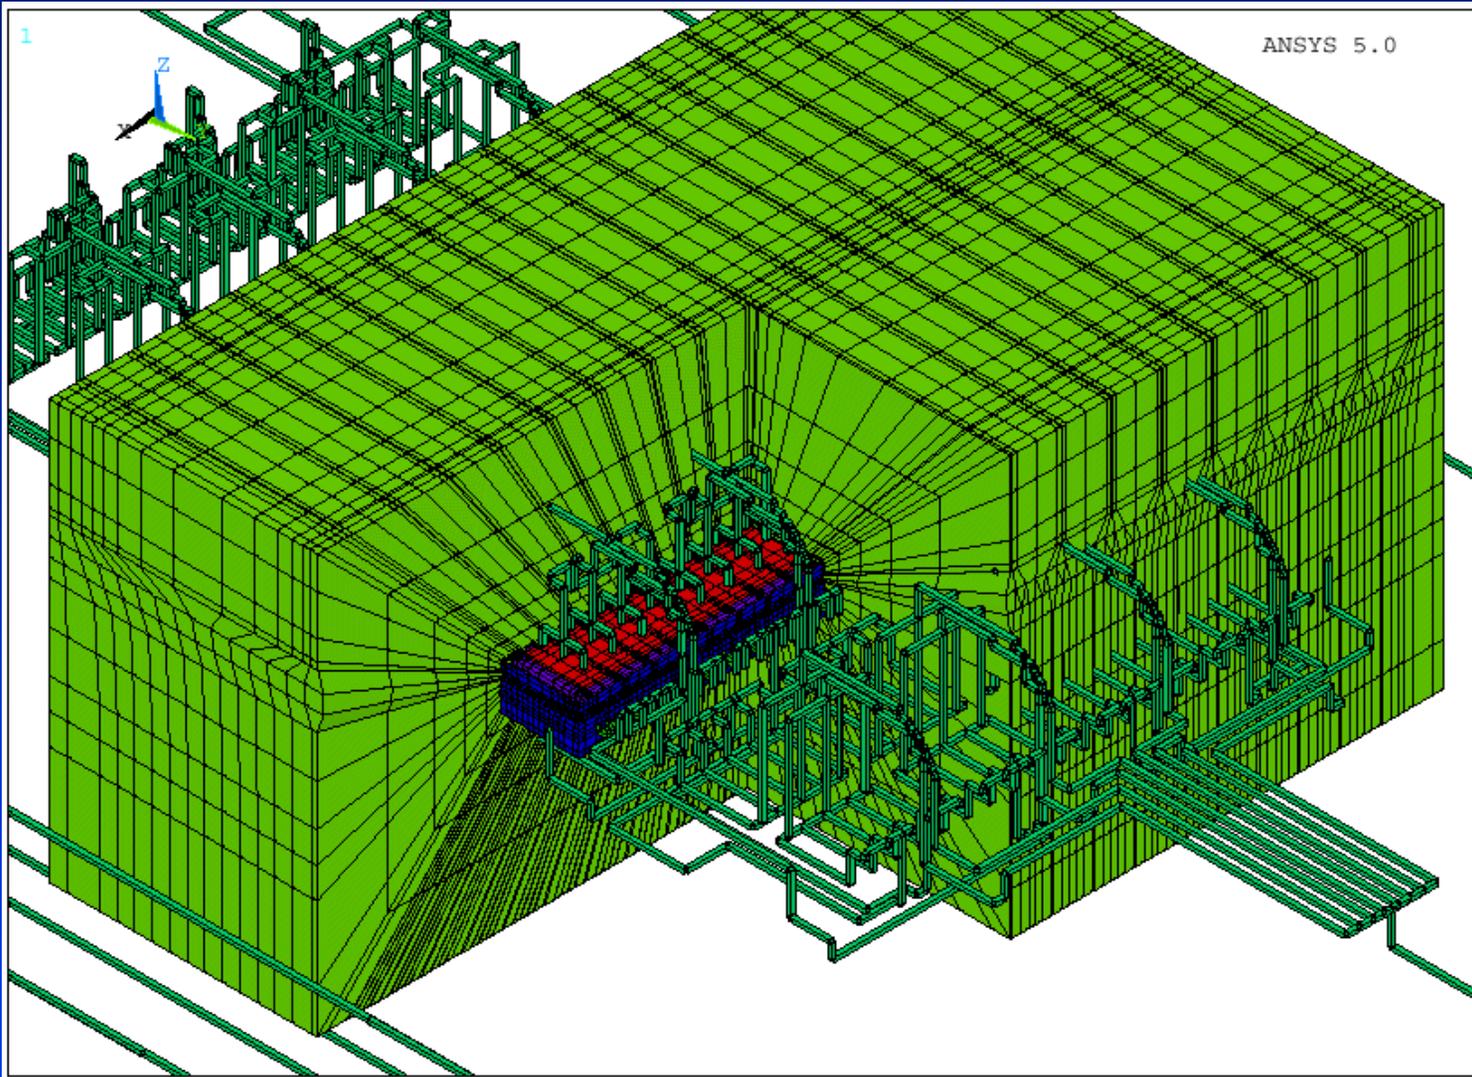

A numerical scheme external to the ANSYS solver must be setup, starting from an assumed initial internal load. The task of that external numerical scheme is to converge toward that cathode block equilibrium condition pressure loading for each element face of the carbon block/side lining interface.

# 1992, 3D cathode potshell plastic deformation and lining swelling mechanical model

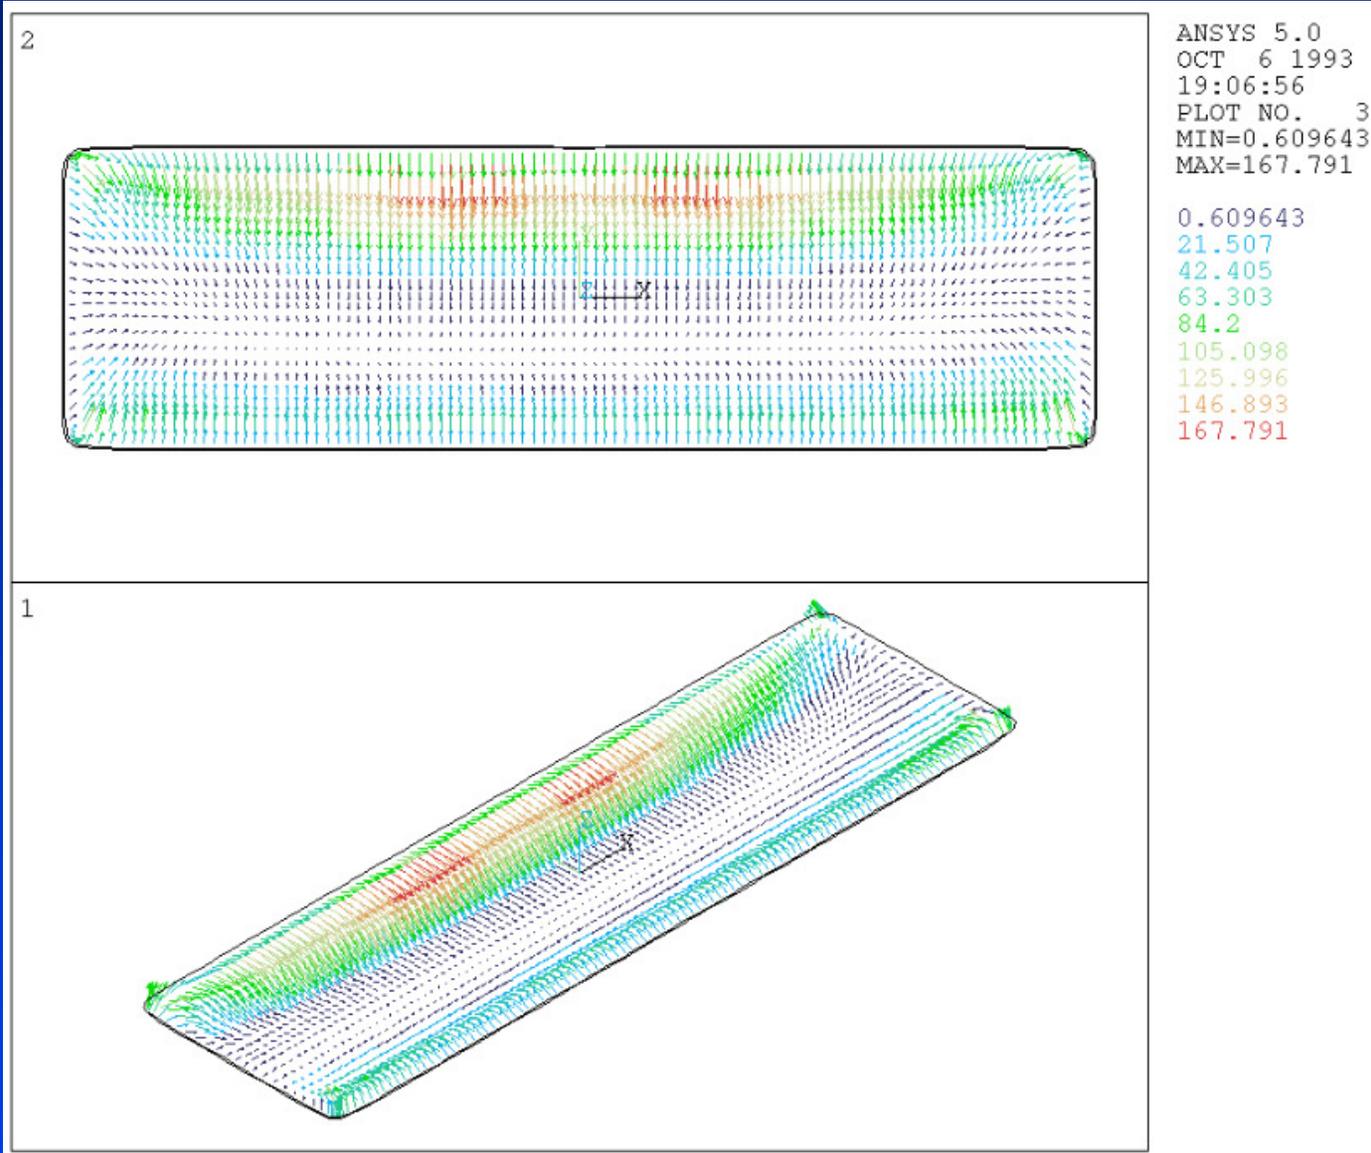

# 1993, 3D electro-magnetic full cell model

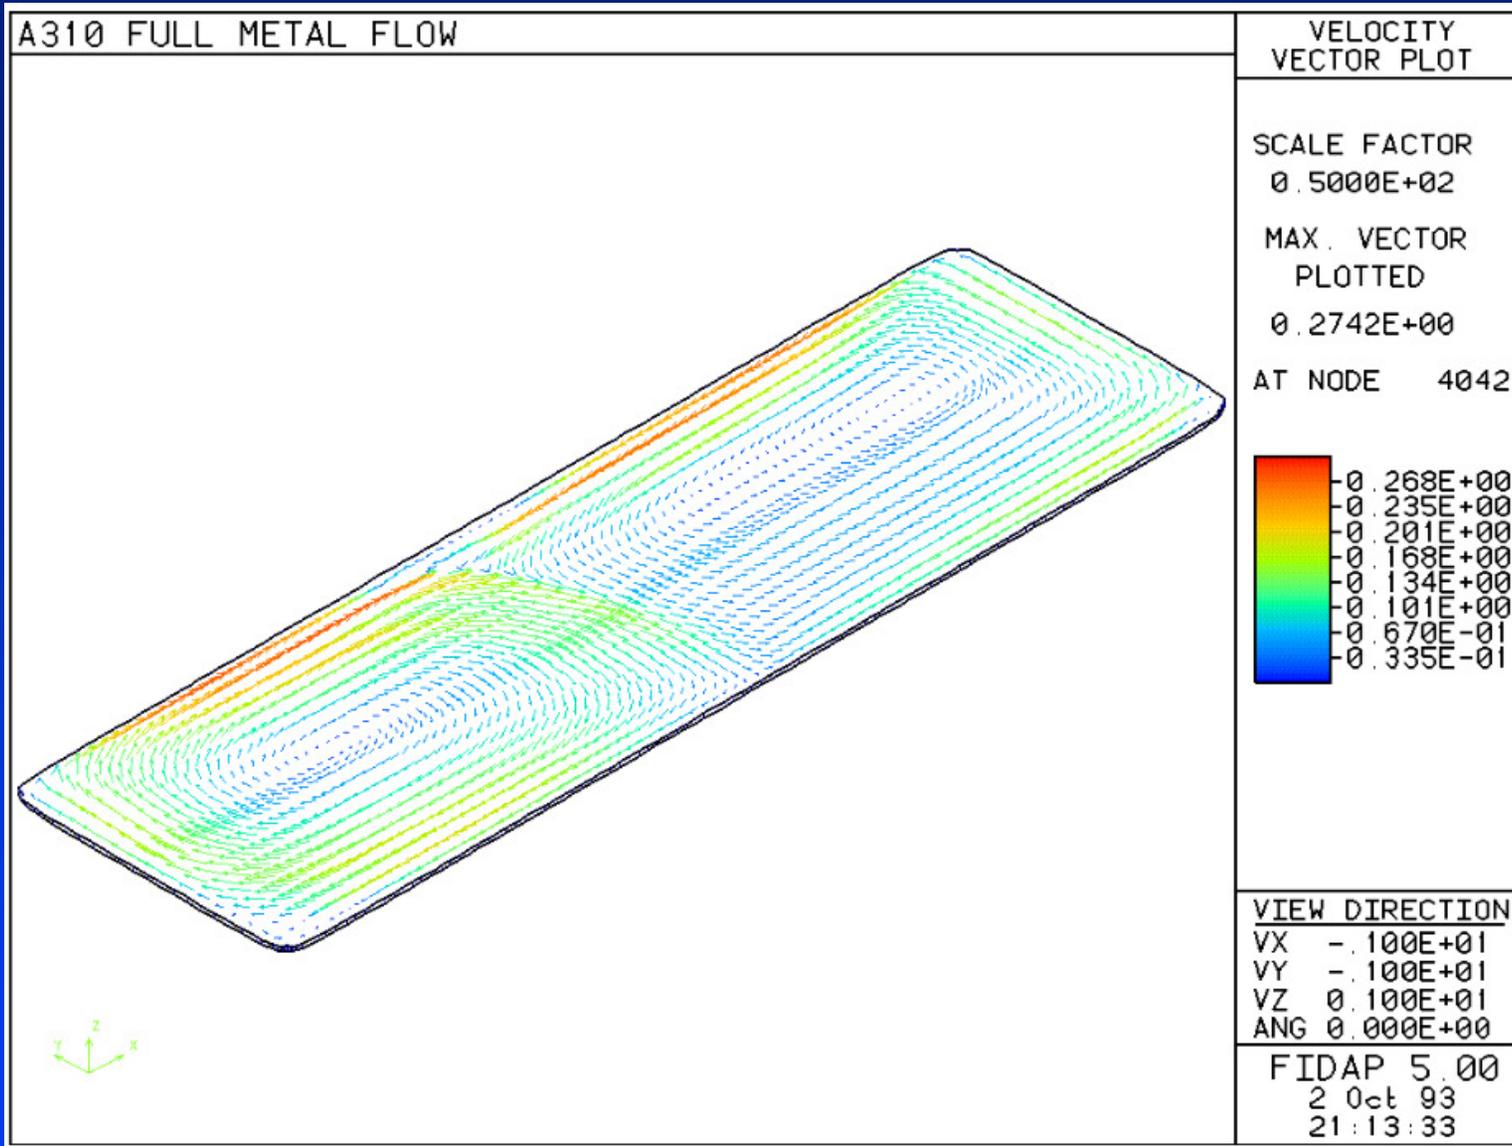

The development of a finite element based aluminum reduction cell magnetic model clearly represented a third front of model development.

Because of the presence of the ferro-magnetic shielding structure, the solution of the magnetic problem cannot be reduced to a simple Biot-Savard integration scheme.

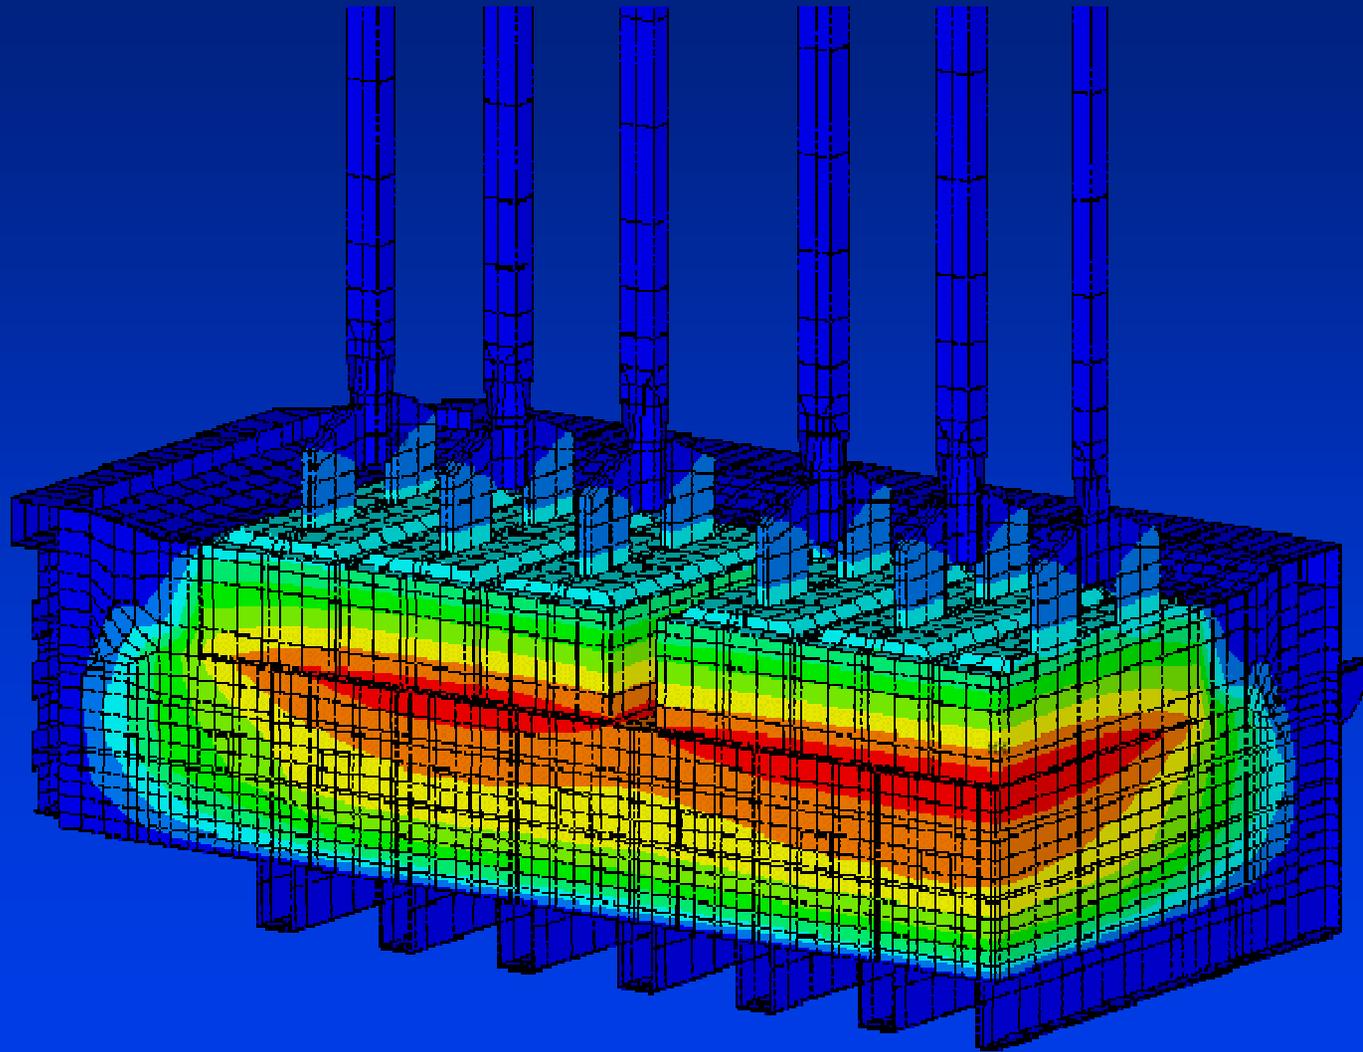

# 1993, 3D electro-magnetic full cell model

# 1993, 3D electro-magnetic full cell model

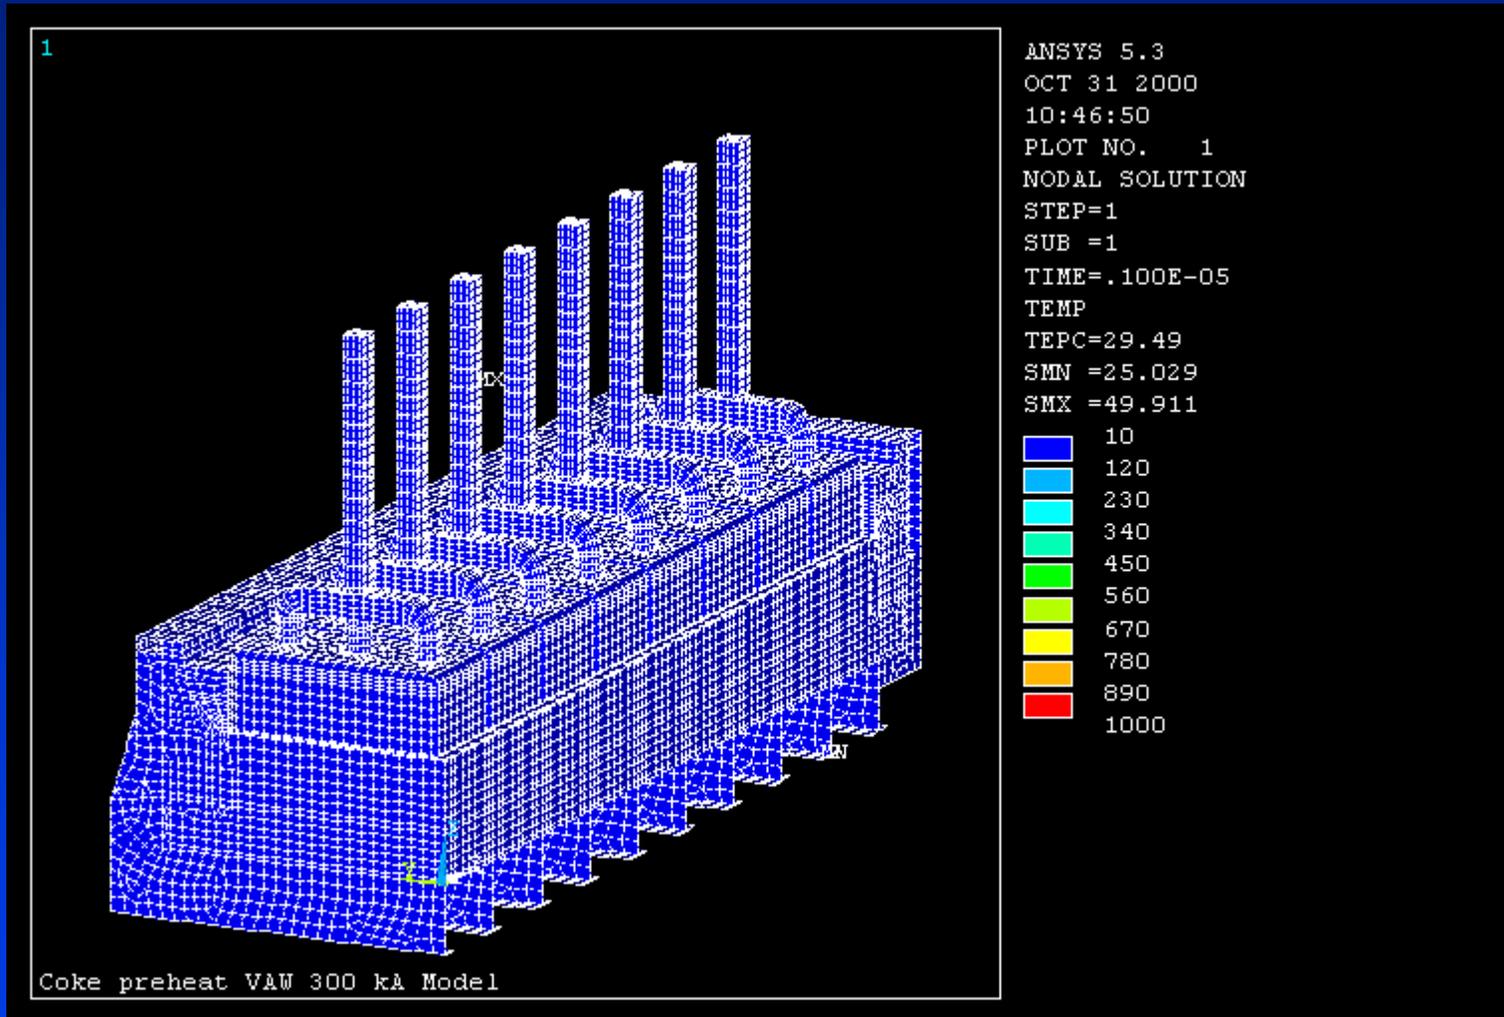

# 1993, 3D transient thermo-electric full quarter cell preheat model

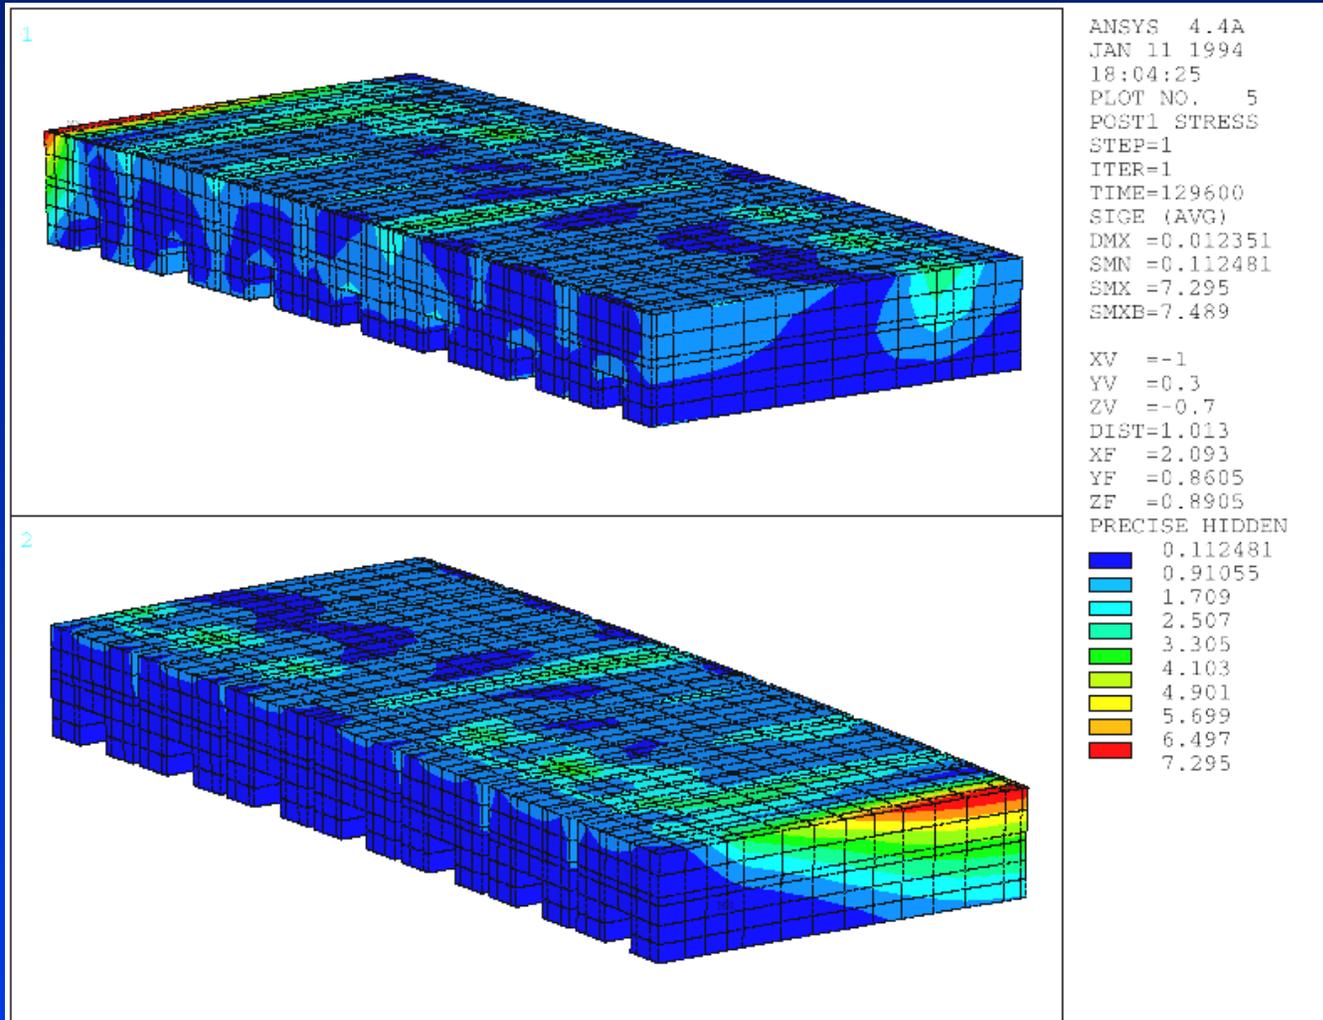

The cathode quarter thermo-electric model was extended into a full quarter cell geometry in preheat configuration and ran in transient mode in order to analyze the cell preheat process .

The need was urgent, but due to its huge computing resources requirements, the model was not ready in time to be used to solve the plant problem at the time.

# Transient Thermal Model Solution

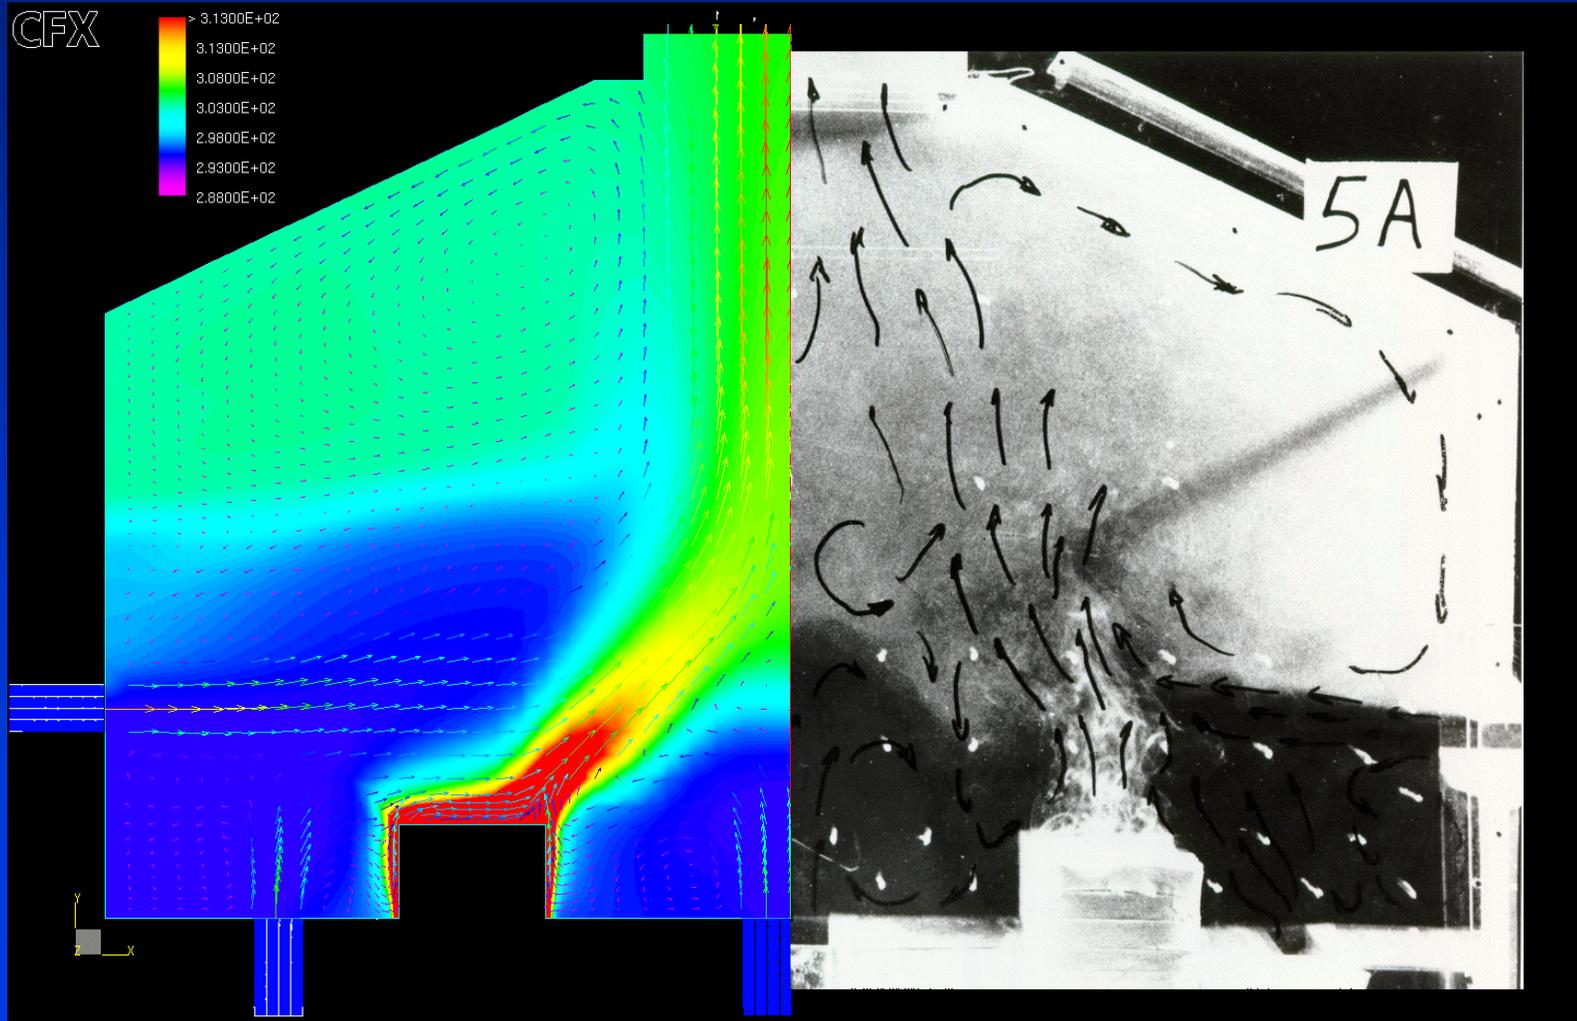

# 1993's Model Extension to Stress Analysis

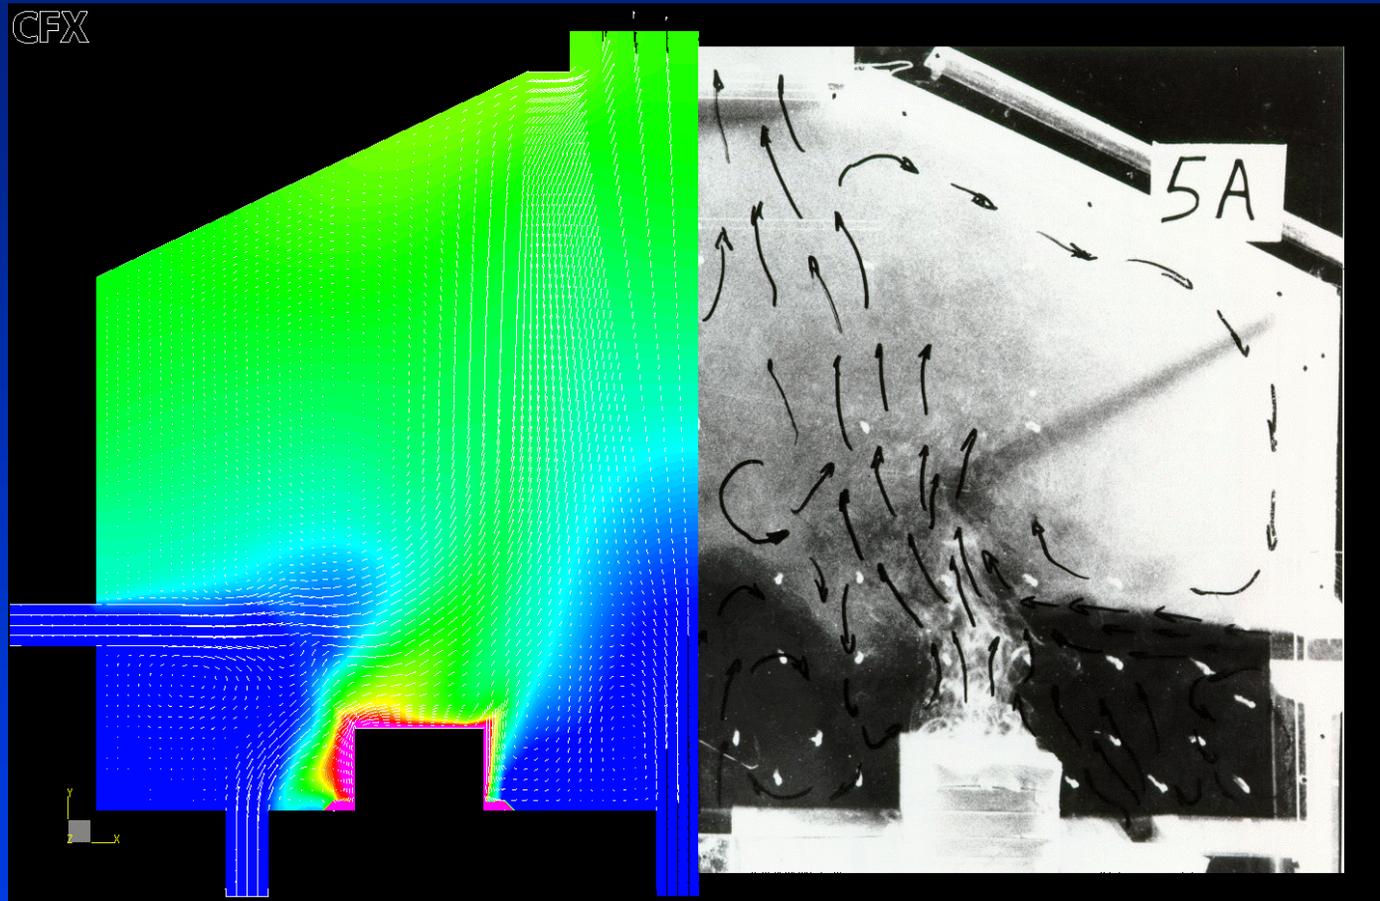

Equivalent stress in the cathode panel at 36 hours – standard coke bed

# 1993, 2D CFDS-Flow3D potroom ventilation model

# 1993, 2D CFDS-Flow3D potroom ventilation model

2D “Reynolds flux” model results vs. physical model results

# 1995, Dyna/Marc Lump Parameters+ Model

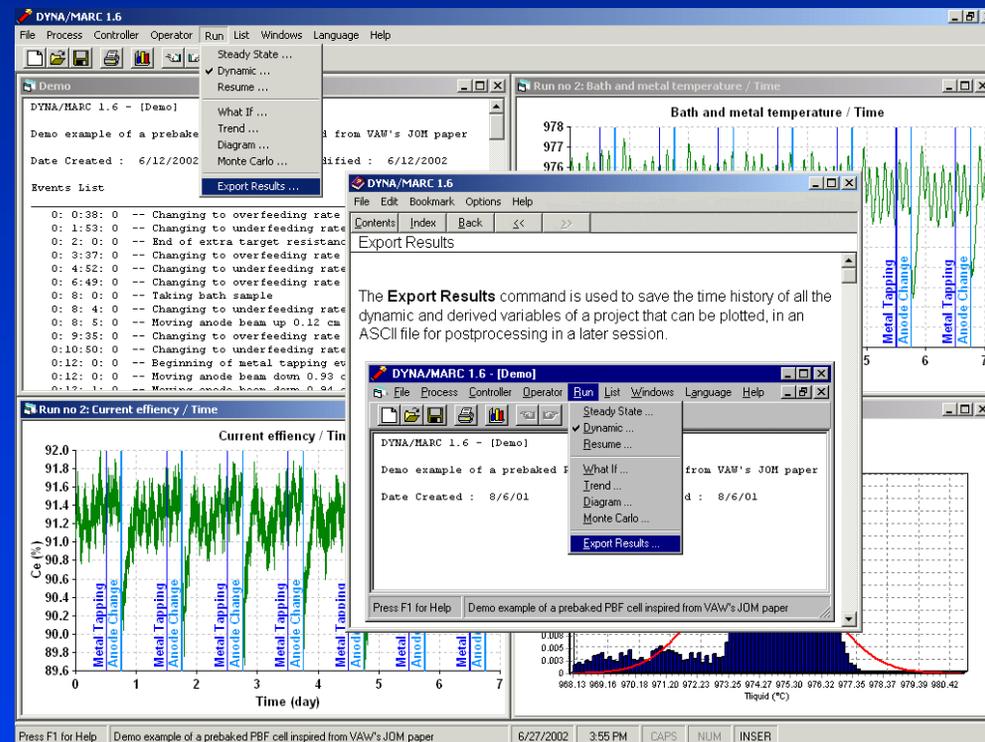

DYNA/MARC (DYNAMIC Model of Aluminum Reduction Cells) is a dynamic simulator of the behavior of aluminum reduction cells.

DYNA/MARC is composed of three different models.

The first is the Process model, that solves the heat and mass balance in the cell. It also takes into account the evolution of the ACD (anode to cathode distance) and the line amperage fluctuation.

The second model is the Controller model. This reproduces the plant controller response based on all the programmed algorithms taking into account the current cell state.

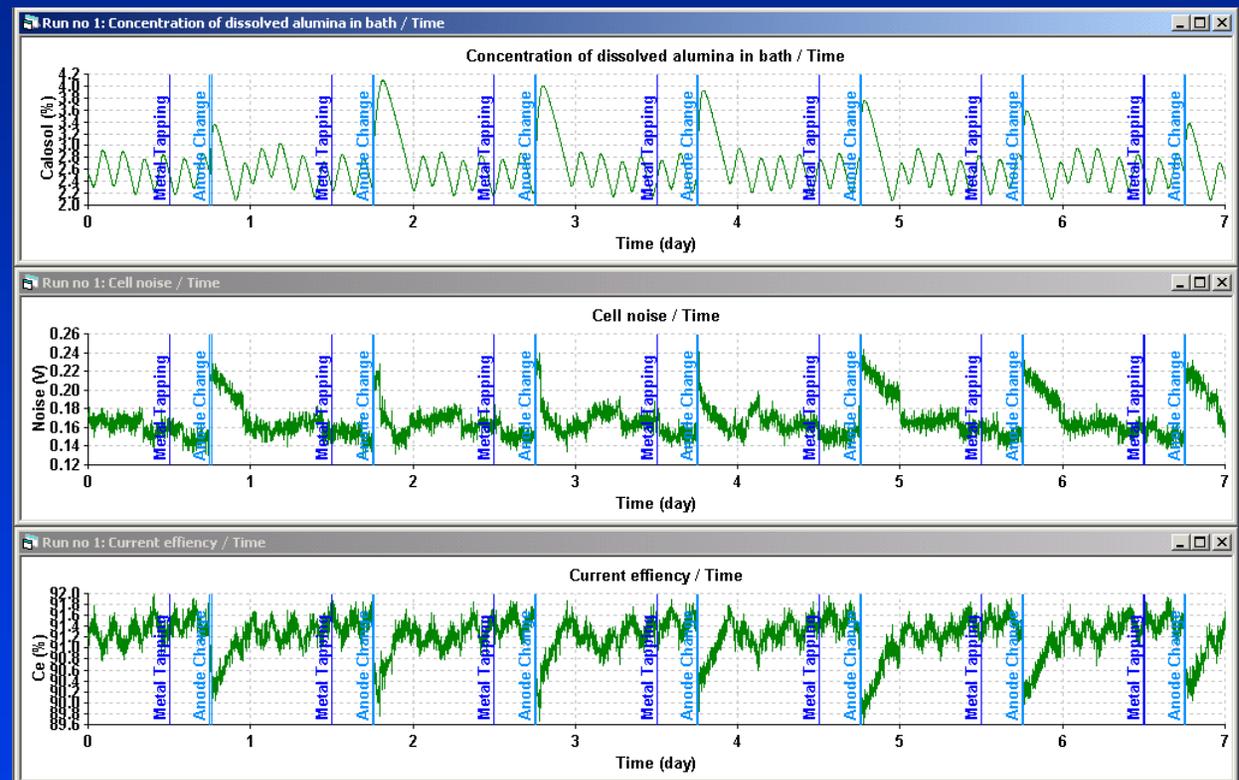

Finally, the Operator model allows the software to simulate the actions undertaken by the operator on his schedule or when the controller requires his intervention.

# 1995, Dyna/Marc Lump Parameters+ Model

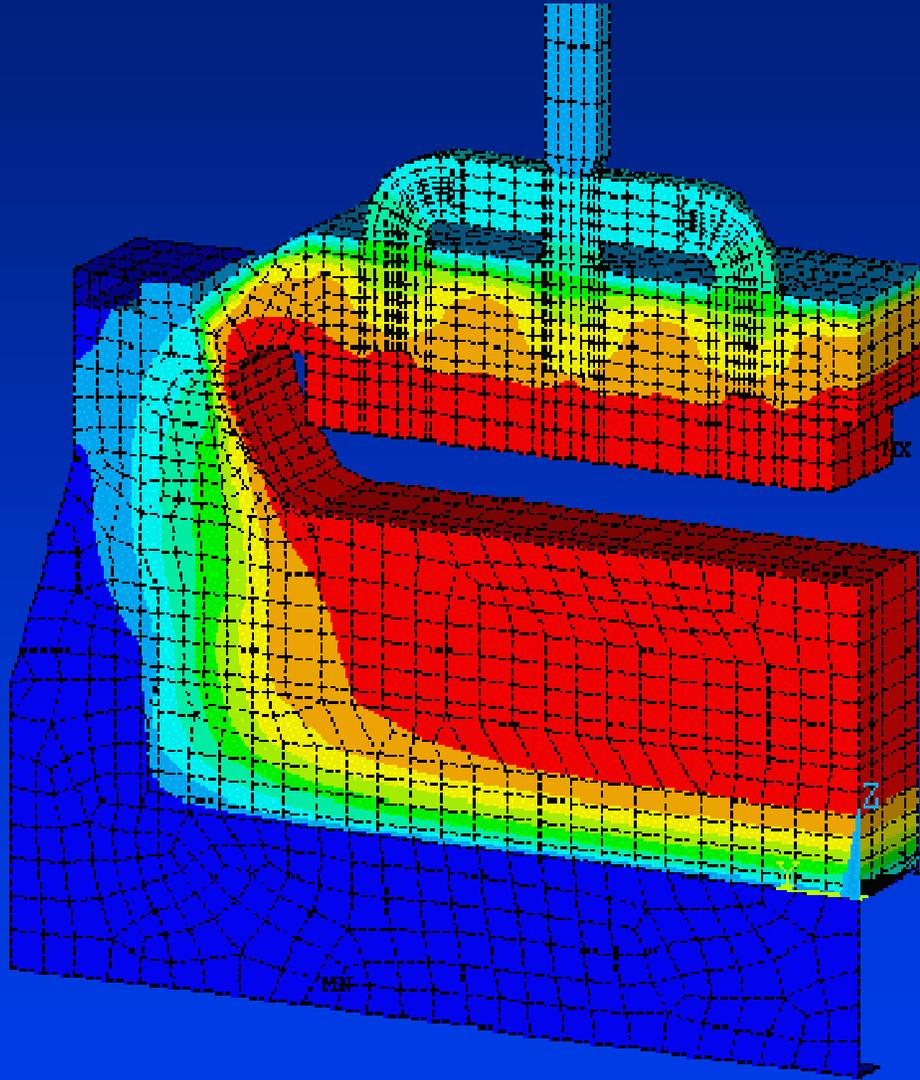

Dyna/Marc can be used to illustrate the behavior of the Hall-Héroult process in the context of a general purpose aluminium electrolysis training course.

For example, it can illustrate the impact of undesirable alumina feeding from the cover material during an anode change on the cell current efficiency.

With undesirable alumina feeding

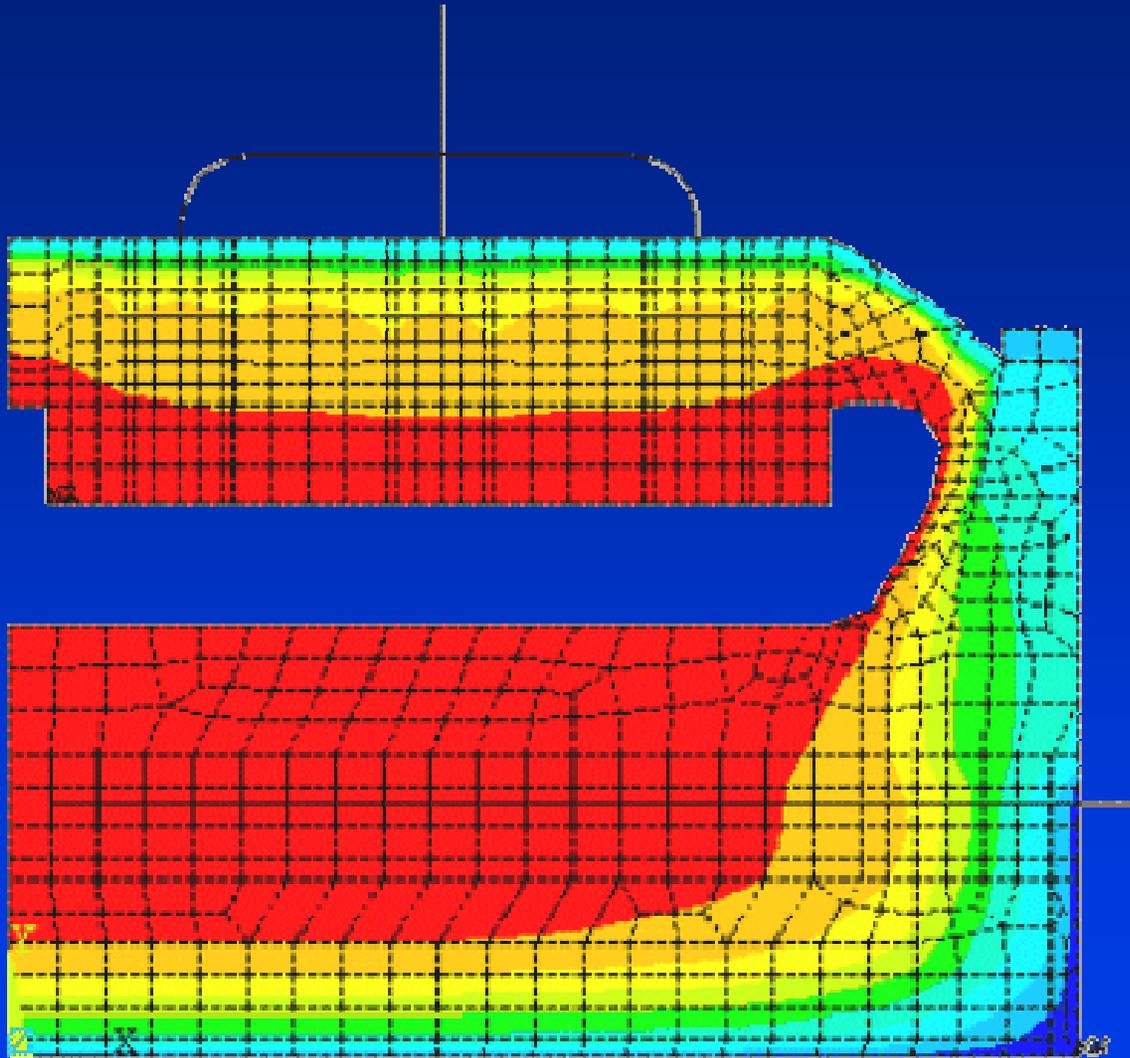

# 1998, 3D thermo-electric full cell slice model

As described previously, the 3D half anode model and the 3D cathode side slice model have been developed in sequence, and each separately required a fair amount of computer resources.

Merging them together was clearly not an option at the time, yet it would have been a natural thing to do. Many years later, the hardware limitation no longer existed so they were finally merged.

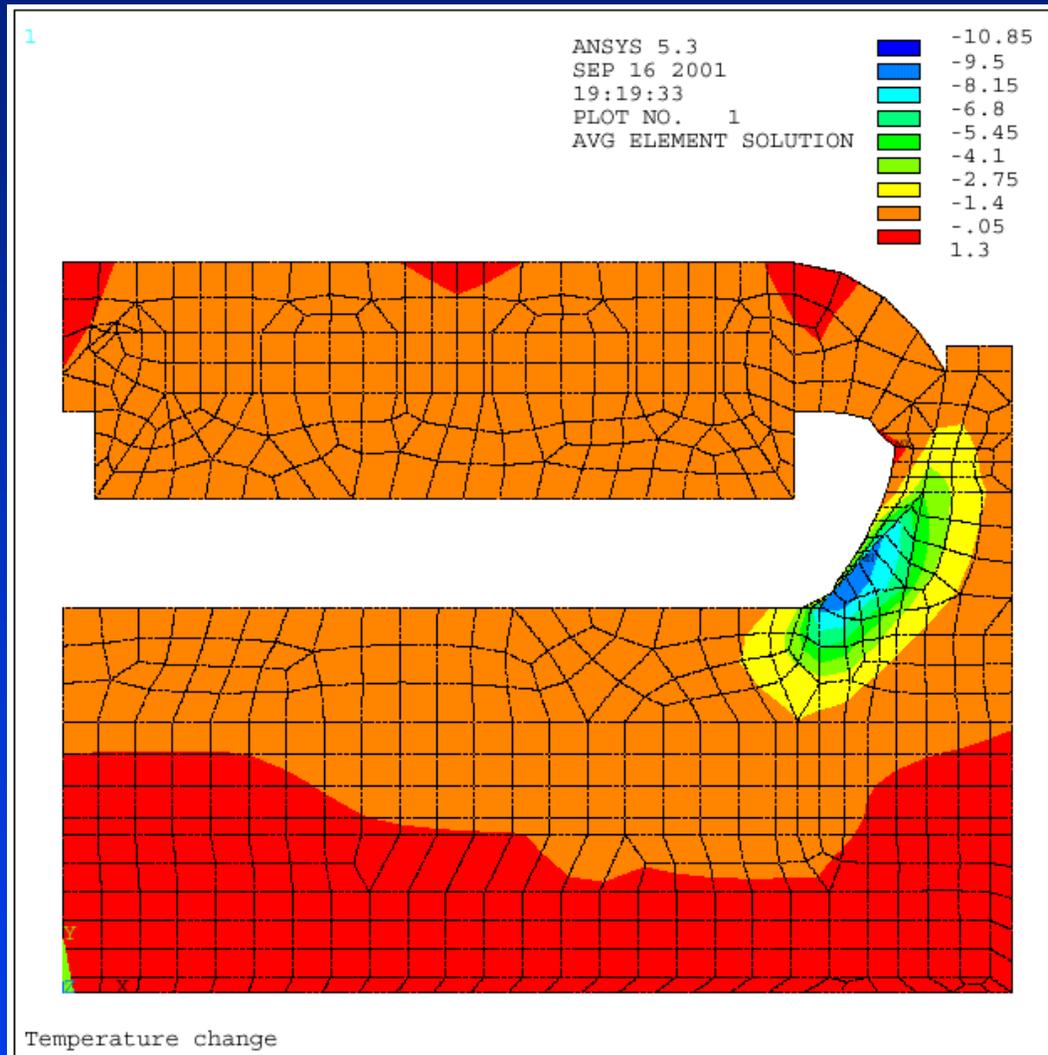

# 1998, 2D+ thermo-electric full cell slice model

2D+ version of the same full cell slice model was developed. Solving a truly three dimensional cell slice geometry using a 2D model may sound like a step in the wrong direction, but depending on the objective of the simulation, sometimes it is not so.

The 2D+ model uses beam elements to represent geometric features lying in the third dimension (the + in the 2D+ model).

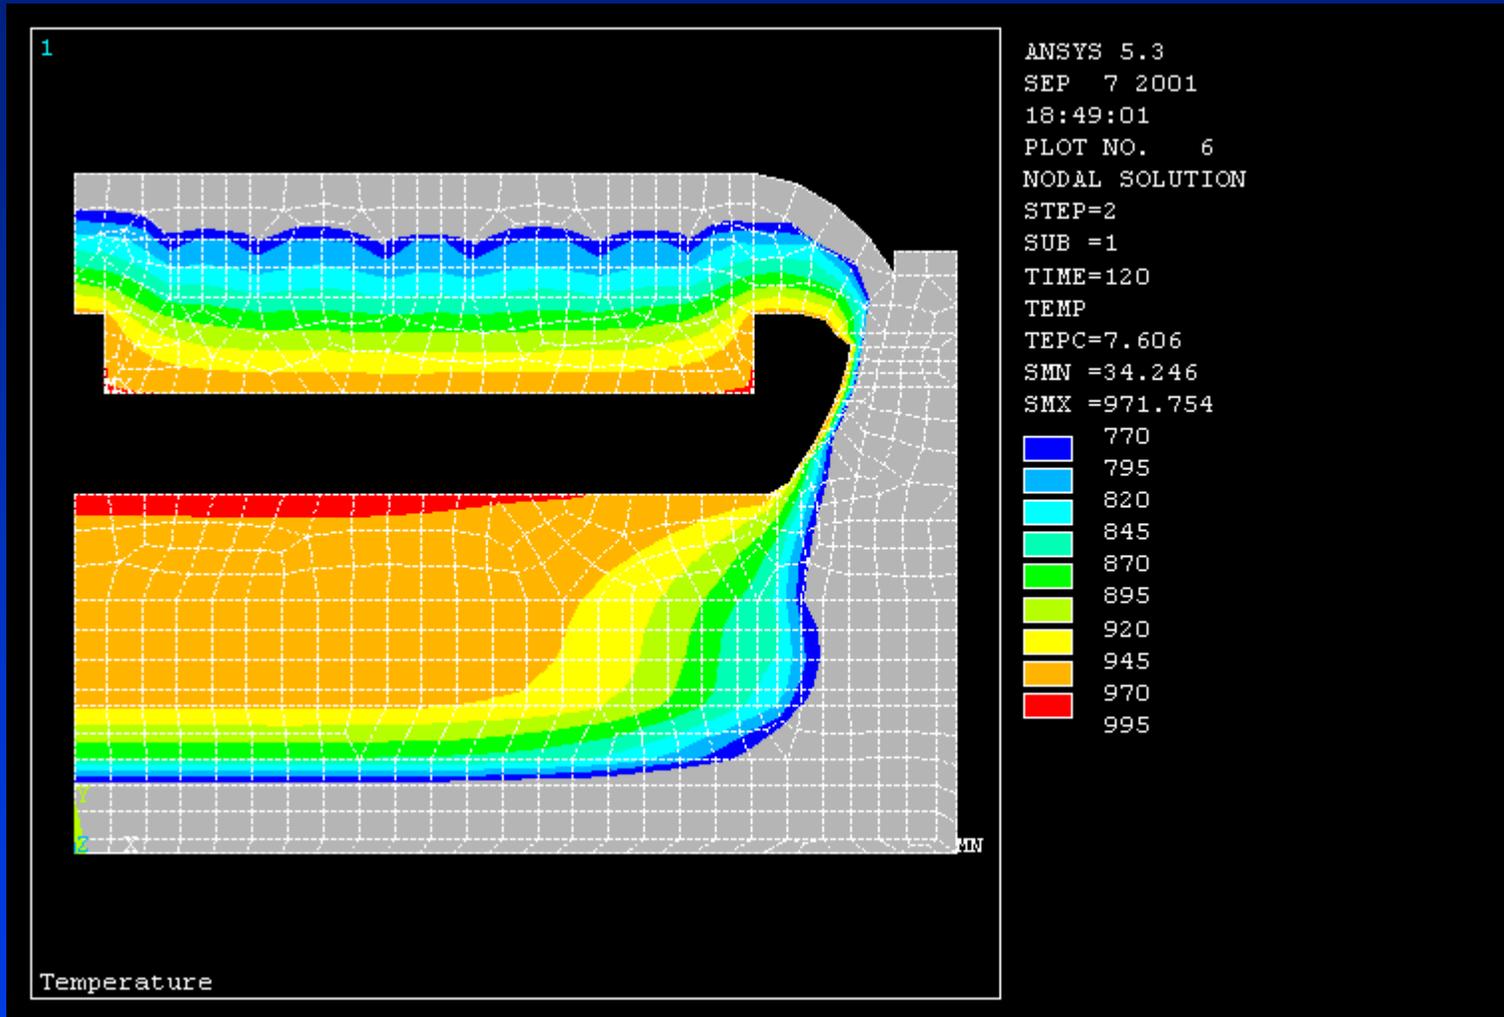

# 1999, 2D+ transient thermo-electric full cell slice model

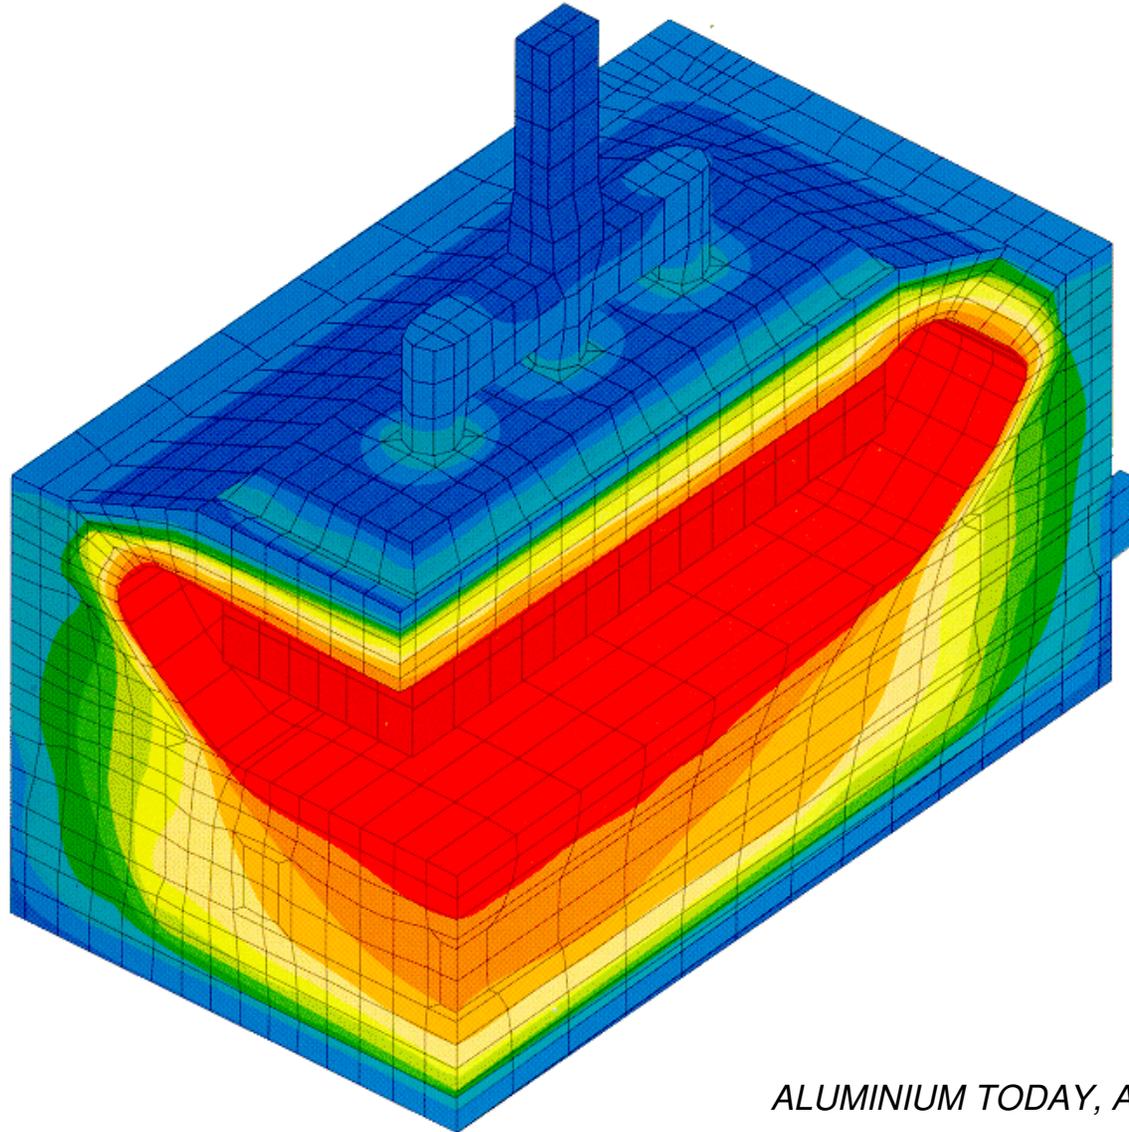

An interesting feature of that model is the extensive APDL coding that computes other aspects of the process related to the different mass balances like the alumina dissolution, the metal production etc.

As that type of model has to compute the dynamic evolution of the ledge thickness, there is a lot more involved than simply activating the ANSYS transient mode option.

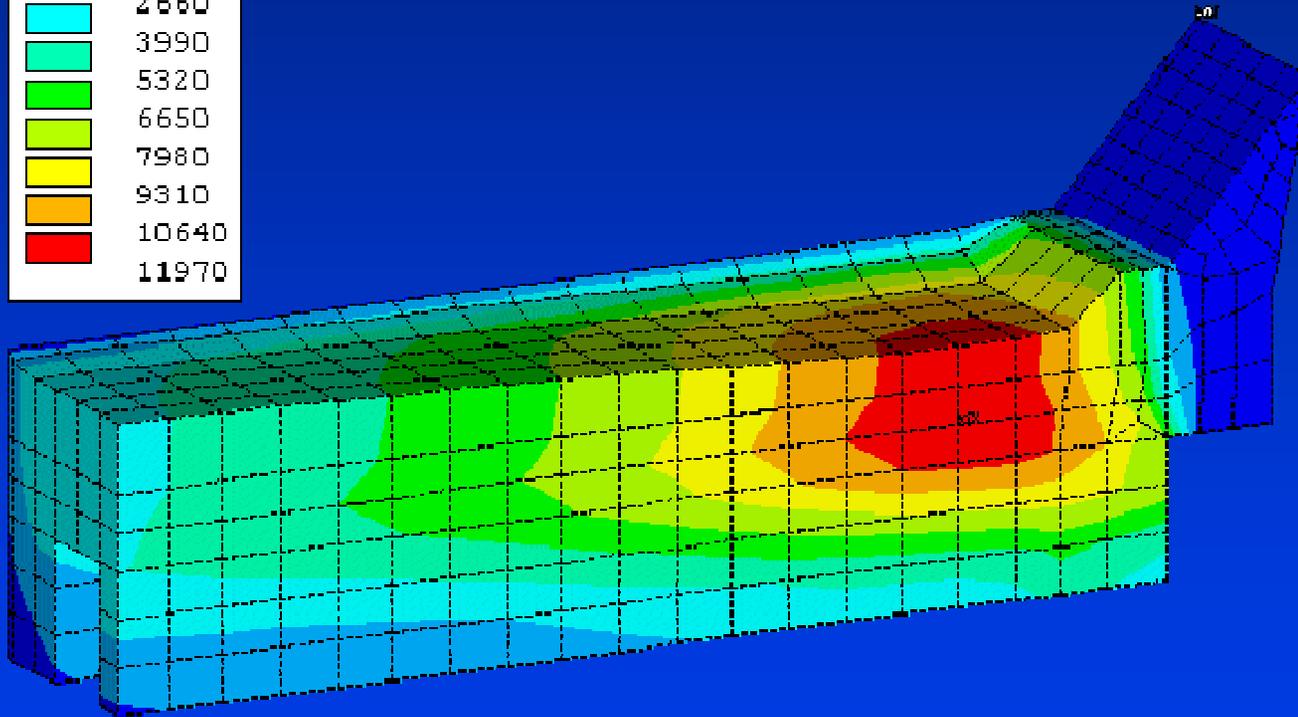

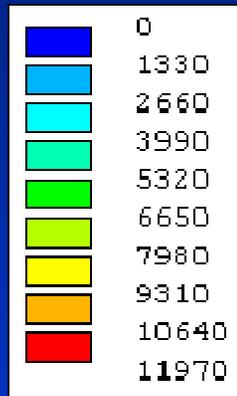

# Modeling Total Power Failure

# Technology key to competitive smelting vaw aluminium today

# 2000, 3D thermo-electric cathode slice erosion model

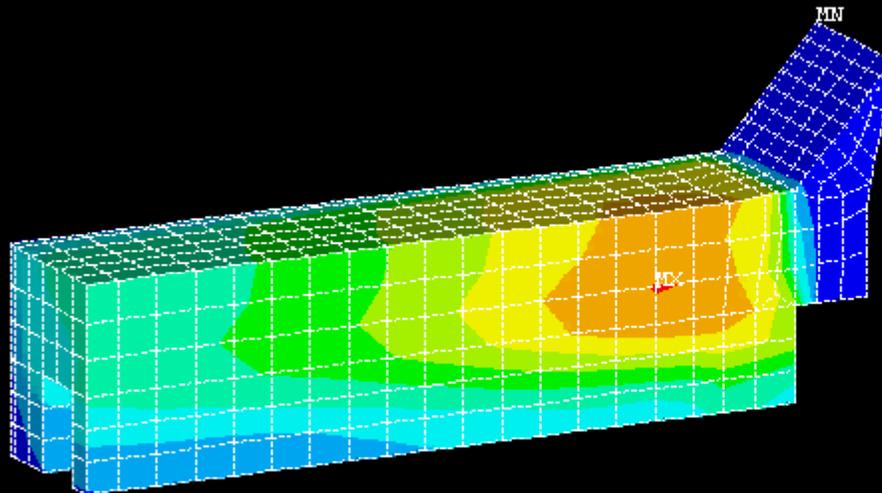

Cathode erosion rate is proportional to the cathode surface current density and that the initial surface current density is not uniform, the erosion profile will not be uniform.

Furthermore, that initial erosion profile will promote further local concentration of the surface current density that in turn will promote a further intensification of the non-uniformity of the erosion rate.

## Résumé

Une cuve d'électrolyse est certainement un investissement majeur pour une aluminerie. Toutes les mesures sont donc prises en main afin de maximiser la production et la durée de vie de ces cuves. Par exemple, les industries font appel à diverses méthodes de préchauffage afin d'assurer une transition adéquate vers la mise en opération de la cuve. Parmi ces méthodes, Sorlie et Øye notent que le préchauffage au gaz est celle qui donne la distribution de température la plus uniforme dans la cuve.

Afin d'être en mesure de prédire correctement le comportement de la cuve lors du préchauffage, il est nécessaire de développer un modèle thermo-chimio-mécanique représentatif de la réalité. Ce modèle permettra de prévoir et de comprendre les phénomènes présents au démarrage de la cuve afin d'optimiser la longévité et les coûts d'utilisation de la cuve.

## Problématique et objectif

Un modèle adéquat des matériaux de la cuve est nécessaire pour détecter les risques d'apparition de fissures dans le bloc cathodique ainsi que le développement d'ouvertures non désirées où le bain d'électrolyse en fusion pourrait s'infiltrer. De plus, la cuisson de la pâte, la nature quasi-fragile des blocs de carbone et les multiples interfaces de contact sont tous des paramètres importants à considérer.

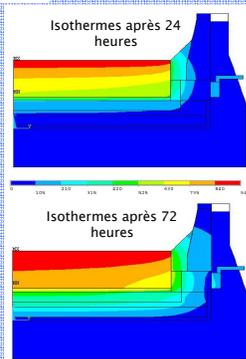

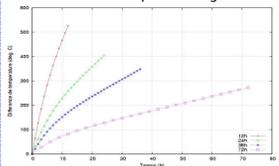

L'objectif est donc de modéliser l'étape de préchauffage au gaz pour un quart de bloc cathodique avec le caisson, le berceau et les matériaux réfractaires correspondant. Une tranche de cuve VAW 300 kA fut donc modélisée à l'aide du logiciel par éléments finis ANSYS et plusieurs simulations avec différents scénarios de préchauffage furent lancées à l'aide du code FESH++.

## Résultats des simulations

### Thermique

– Les gradients thermiques dans le bloc cathodique diminuent lorsque la durée de préchauffage augmente

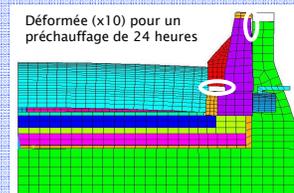

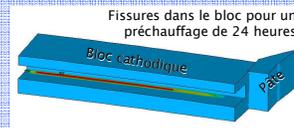

Différence de température sur la hauteur du bloc cathodique en fonction du scénario de préchauffage

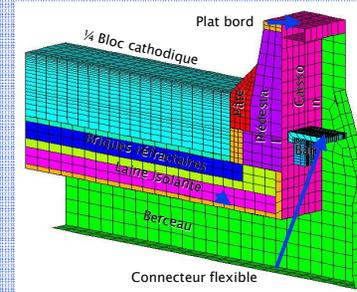

### Mécanique

– En admettant P3 comme plan de symétrie, des fissures se développent dans les ailes du bloc. Ces fissures sont absentes si P3 n'est pas considéré.

– L'expansion du bloc ne peut se faire qu'au dépend de la pâte si P3 est considéré comme un plan de symétrie. Des ouvertures se créent alors et l'électrolyte en fusion y est libre de s'infiltrer.

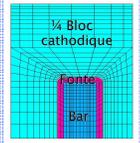

## Développement du modèle

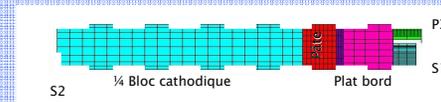

### Propriétés des matériaux

- Coque 2D – Thermomécanique
- Berceau, Caisson, Plat bord
- Brique 3D – Thermique
- Connecteur flexible, Briques réfractaires, Laine isolante
- Brique 3D – Thermomécanique – Élastique
- Bar collectrice, Fonte
- Brique 3D – Thermomécanique – Quasi-fragile
- Piédestal, Bloc cathodique
- Brique 3D – Thermo-chimio-mécanique – Quasi-fragile réactif
- Pâte à brasquer

### Conditions aux limites

- S1 et S2 : Plans de symétrie pour le bloc cathodique
- P3 : Fondation élastique qui dépend du confinement des matériaux le long de la cuve

### Scénarios de préchauffage

- Coefficient de transfert thermique de 650 W/m<sup>2</sup>K
- Température finale de flamme de 955 °C
- Rampe constante
- Durée du préchauffage : 12, 24, 36 et 72 heures

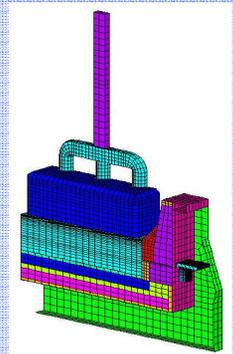

## Travaux futurs

### Comportement thermo-électro-chimio-mécanique d'une cuve de Hall-Héroult lors d'un préchauffage électrique

- Modélisation de l'anode
- Insertion du lit de coke
- Comparaison des résultats avec ceux d'un préchauffage au gaz

### Comportement d'un quart de cuve de Hall-Héroult lors d'un préchauffage électrique ou au gaz

- Modélisation complète du quart de cuve incluant le coin
- Comparaison des résultats avec ceux d'une tranche

# CHALLENGES IN STUB HOLE OPTIMISATION OF CAST IRON RODDED ANODES

## Multiphysics Contact

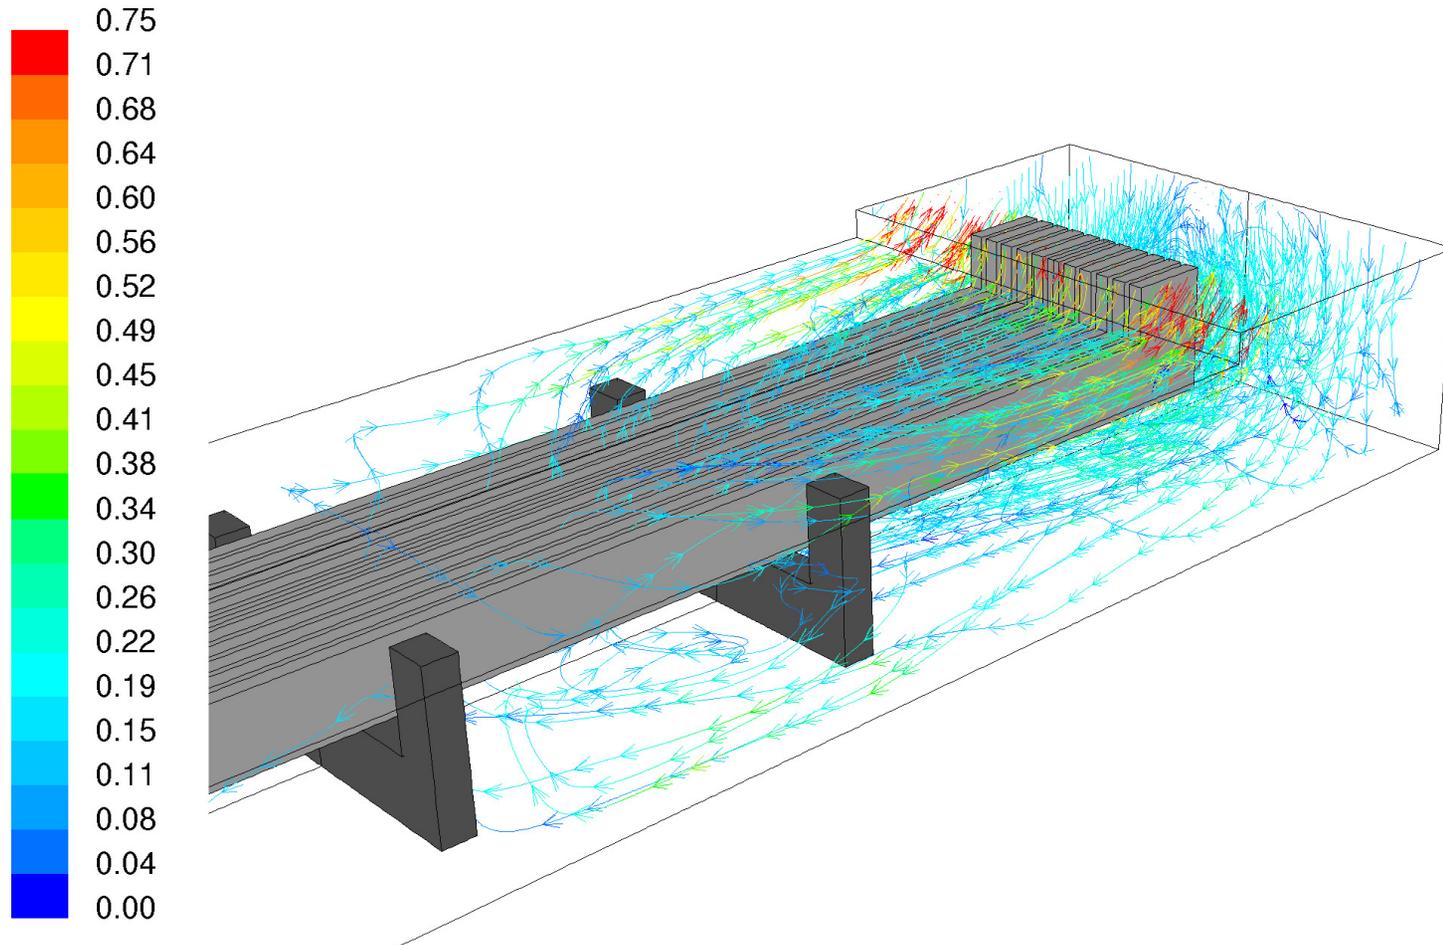

Surface-to-surface multiphysics contact, including the effects of thermal contact conductance, electrical contact resistance and Joule heat generation at the interface, was developed and implemented by Goulet in the in-house finite element toolbox *FESh++* using modern Object-Oriented techniques. The use of algebraic equations to specify the material properties allows the direct implementation of the electrical contact resistance equations derived by Richard *et al.*
